3547	29th	1163 - 1202	277 - 280

INDEX TO VOLUME II FOR 1928.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Renal and Kidney, Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc., Child and Infant, Bronchocele, Gout, and Thyroid, Diabetes, Glycosuria, and Sugar, Light, Roentgen, Radium, X Rays, Status Lymphaticus and Thymus, Eye, Ophthalmia, and Vision, Bicycle and Cycle, Motor and Automobile, Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

A

- ANNEY Mary L. (and Harry E. Mock) Occupational statistics 618
Abdomen acute from the general practitioner's point of view (D. Innes) 933
Abdomen lower, acute conditions in (W. W. Chipman) 300 475
Abdominal aneurysm See Aneurysm
Abdominal diagnosis, failure of x rays in (Herbert J. Paterson) 249, 595- (F. Herniman Johnson) 598 — Discussion 249 — Leading article 617 — Correspondence on 678 772 See also x rays
Abdominal friction in peritonitis (Walter Broad bent) 1036 — Correspondence on 1156
Abdominal supports 533
Abdominal tumor See Tumor
ANZL, A. Lawrence Congenital oesophageal obstruction 45 (O)
Aberdeen See Scotland
Abortion and shock 129
ANNAHAUS A. (and H. M. ANNAHAUS) Training for Athletes rev 18
ANNAL, Sir George Stewart obituary notice of
Abscess alveolar overlooked (C. Oralian Maasbee) 13
Abscess brain drainage in (Sir Percy Sargent) 308 971 — Discussion 308
Abscess of liver tropical acquired in England (J. Campbell Gilroy) 529 See also Amoebiasis and Bacterial flora of Intestine
Abscess retropharyngeal secondary to foreign body in hypopharynx (D. Lindley Sewell) 1135
Acadêmico de Medicina — B O C The need for statistical inquiry 950 1058
Acadêmico de Ciências The fight against yellow fever 1059
Academy of Medicine of New York inaugurates a course in diseases of old age 95
ACADEMY ROYAL OF MEDICINE IN IRELAND
Section of Obstetrics — Cancer of the cervix 1137 — Uterine fibroids 1138 — Amputation of the Fallopian tube 1138
Section of Pathology — Cancer of the lung 1135 — Embryoma 1139 — Spinal adenoma 1139 — Boveri's cerebro-spinal fluid test 1139 — Bithridiocephalus infestation 1139
Accidents Among boys in coal mines (parliamentary note) 38 — Motor and voluntary hospital (parliamentary note) 81 — Industrial (parliamentary note) 134 — In industry Inter national Labour Office brochure on 181 — With railway carriage windows 228
Achalasia of the cardia so-called cardiospasm 1110
Achoondroplastic twin (Allan Warner) 983 (O)
Achoondroplastic review of book on 669
ACHES E. Loine — Helen Henson a Memoir rev 1142
Acto Medica Scandinavica Supplementum xxvii A Study of Glucosuria with Special Reference to the Interpretation of the Incl. Finding of a Positive Reduction Test (Hagvin Malmgren) 737 — Supplementum xxvii Investigation of the Concentration of Lactic Acid in Blood and Urine under Physiologic and Pathologic Conditions (Otto Jervell) rev 913
Acto Pediatrico vol. viii, rev 615
Acticle eyeshine mirrors 828 See also Mirrors
Actinomyces pulmonary (T. Warwick Preston) 1172 (O)
Actinotherapy clinics for 676
Actinotherapy control of (W. E. Dixon) 642 — (C. B. Head) 644 — Leading article 661 See also Ultra-violet
Actinotherapy in dental caries (F. Talbot) 853
Actinotherapy in certain skin diseases (W. J. O'Donovan) 853
Actino-therapy and Ultra violet Radiation The effect of the apparatus of the Cox Cavendish Electrical Company 35
Acute abdomen See Abdomen
ADAM James The nature and treatment of asthma 612 — Chronic nasal sinusitis with mental symptoms 794
ADAM J. A. Wilfred Pancreatitis 300
ADAMS E. W. The reprint plague 586
ADAMS F. Shirley (and others) Splenomegaly, purpura with high blood pressure 1912 (O)
ADAMS F. Shirley (and others) Splenomegaly, purpura with high blood pressure 1912 (O)

- ANALYSIS Mr. Tumours of the spinal cord 200

An Address ON THE PROBLEM OF CANCER*

BY
SIR G. LENTHAL CHEATLE, KCB, CVO,
FRCS,
SURGEON AND LECTURER IN SURGERY, KING'S COLLEGE HOSPITAL,
LONDON

MR. PRESIDENT,—Before discussing the problem of carcinoma I must emphasize the importance of isolating all forms of hyperplasia from the processes now described under the comprehensive term "inflammation." All authorities in pathology agree that so-called "chronic inflammation" is a different process from "acute inflammation." The inclusion of so many different processes under one term compels me to say that the time has come to orientate afresh the present chaotic outlook on the subject of "inflammation" and to discover how the matter can be simplified. I urge the limitation of the term "inflammation" to the circulatory disturbances which occur inside and outside injured and structurally intact blood vessels, provided the injury does not cause their death. I exclude all forms of hyperplasia from "inflammation," and by hyperplasia I mean that process where one cell begins to divide into two cells, therefore, I would exclude from the subject of "inflammation" the formation of granulation tissue and the healing of wounds, and place them under the term "hyperplasia," of which they are very beautifully controlled and regulated forms, the laws governing which are slowly beginning to dawn upon us. If all forms of hyperplasia were included in one self-contained subject important changes in our conception of many things would necessarily follow. For example, the condition now described as "chronic mastitis" would not be regarded as an "inflammatory" process. The desquamative epithelial hyperplasia and the hyperplasia of the pericanalicular and periacinous connective tissue containing lymphocytes, which are characteristic of so-called "chronic mastitis," will be seen to have a fundamental physiological significance when they are compared with the precisely similar changes in breasts of newly born male and female children and of females at puberty and lactation. "Chronic mastitis" is really a state in which physiological activity becomes pathological by being present when the breast should be at rest. It is not an inflammatory condition at all. Again, the cellular flora evoked by the irritation of the tubercle bacillus is an example of the importance of considering the morphological effects from the point of view of hyperplasia, instead of regarding them merely as "inflammatory" in origin. The importance of the point lies in this respect: all the connective tissue cells are in contact with the irritant at the site of inoculation, yet the cells which undergo hyperplasia are only the endothelial cells which produce the epithelioid and giant cells of a tubercle. This fact shows that there is a mutual affinity, so far as hyperplasia is concerned, between the irritant and endothelial cells only.

Take another example. Gonococcal infections can induce formation of papillomata, showing that only the epithelial cells responded by hyperplasia to the irritant, although many other types of cells are in contact with it at the same time. I give this as an example of gonococcal selection for epithelium, knowing full well that certain observers—Dr. G. M. Findlay of the Imperial Cancer

Research, for example—believe that the formation of papillomata of the skin in gonorrhoeal infections is not due to the gonococcus but to the presence of an ultra-microscopical organism which is capable of inducing warts in other situations also. In any event the formation of papillomata is a decisive example of a selective action between the products of micro-organisms and one type of tissue cells only.

Before leaving the subject that concerns the relationship between direct irritation of epithelium and the formation of papillomata I must point out that formation of papillomata is of frequent occurrence in premenial epithelial hyperplasia of the large and small ducts respectively in carcinoma of the breast. Lastly, the staphylococcus, when inoculated into the subcutaneous tissue, induces the hyperplasia of fibrous tissue in two parts—(1) as a process of repair in the parts that are killed, and (2) in the strands of fibrous tissue which surround the lesion.

There is another important example of the necessity to separate hyperplasia from "inflammation." It is pretty widely held, and I believe wrongly held, that the dilatation of the blood vessels and also increase in their number causes hyperplasia. John Hunter appears to have maintained this thesis, and in order to demonstrate that hyperplasia occurs as the result of increased blood supply he transplanted a cock's spur into a cock's comb, expecting that in consequence the cock's spur would undergo hyperplasia. His expectation was fulfilled, and the spur underwent an enormous increase in size. I repeated Hunter's experiment and, besides transplanting one spur into a cock's comb, I transplanted at the same time the other spur under the skin of the cock's back. These transplanted spurs underwent about the same amount of hyperplasia during the time they were under observation. I had to kill these birds before I wanted to because the noise they made interfered with the classes in King's College and with the amenities of several business offices in its neighbourhood. During the operation of transplanting the spur into the cock's comb there was decided hæmorrhage from the wound made by excision of the spur, and there was no hæmorrhage when I incised the cock's comb, which appeared to me to consist of gelatinous, glutinous, avascular structure. The comb is vascular only when it is erect. By planting the spur into the comb it did not appear to me that I was placing it in a more vascular medium. Then what could be the explanation of Hunter's transplanted spur? The explanation seems to me to be this—that in its new situation it was not subjected to the wear and tear of life it met with in its normal position, and in consequence grew into enormous proportions. There are many other examples of continuation of growth occurring in the structures not subjected to the ordinary normal wear and tear of life—the claws of animals, for example. However, let us suppose for a moment that Hunter was right, that this cock's spur became so large because it was receiving a greater supply of blood than normal. If this were so Hunter's experiments would have raised the following much more vital problem of hyperplasia: if a comb were able on account of its presumed enormous blood supply, to induce hyperplasia in another structure, why did the comb itself cease growing?

Beyond what I have stated I do not consider that Hunter's experiment proved anything at all. In granulation tissue there is a vast amount of new blood-vessel formation, but when it has been covered by epithelium and ends in a scar these new blood vessels all atrophy. Why should this be so? The answer is perfectly clear to me. It is the hyperplasia of granulation tissue formation that demands the increased blood supply, and when the

* Delivered before the American Medical Association on June 15th.

demand is over the large vascularity is no longer necessary to maintain the life of the cicatrix, and consequently the blood vessels disappear. So far as I am concerned, it is a law that the demand of hyperplasia induces vascularity, and hypoplasia is not induced by an increased blood supply.

I pass on to the hyperplasia which more intimately concerns carcinoma. There are decided indications in breast pathology that an addition should be made, with all due care, to the present limited conception of the morphological appearances of carcinoma. All pathologists agree that carcinoma exists when epithelial cells can be seen invading alien country, whence they grow and from which they are disseminated and grow in different parts of the body. My statement that an addition to the morphological status of carcinoma is essential is based upon what I consider to be a law—namely, that before epithelial cells invade the parts outside the normal boundaries of ducts and acini there has been malignant epithelial hyperplasia within them, and that the process of carcinoma really begins before invasion occurs. I can see in every early carcinoma of the breast the presence of this malignant change within the normal boundaries of ducts and acini. It can frequently be discovered in advanced carcinoma in microscopical sections that have been made in series of the whole focus of primary disease. The epithelial cells outside the normal boundaries possess the same morphological appearances as those inside. I feel sure that the epithelial hyperplasia inside the normal boundaries is malignant and that it is the source of supply to the invading cells.

I now show you a state of things which can be commonly demonstrated in breast lesions which are not now generally considered to be carcinoma. Here are terminal ducts and acini that are filled by an epithelial hyperplasia that cannot be distinguished from the invading cells of carcinoma in other specimens, but here they are all enclosed in normal boundaries. This type of lesion usually occurs in the breasts of females before the carcinoma age. This specimen I removed from a woman of 25 years. I believe the catastrophe of carcinoma here was a question of time and opportunity, and that this lesion represents the true precancerous stage, and can be regarded as malignant if not carcinomatous. I may here state that I have never seen in the earliest examples of carcinoma of the breast this malignant change occurring in the acini alone, the terminal ducts as well have always contained the malignant epithelial hyperplasia. In all instances the elastica must be stained to make sure that the cell-containing spaces are dilated ducts.

Before leaving this part of my subject I would like to state definitely that by morphological examination I can never detect any visible indication of a local attempt to arrest the process of carcinoma. Some people have suggested that the enormous hyperplasia elastica around the ducts and even the acini, which I have shown sometimes occurs in carcinoma, is an indication of an attempt to bar its progress. All I can say on this matter is that hyperplasia elastica is rare in breast carcinoma and when present has proved to be inefficient, and that hyperplasia elastica occurs frequently round ducts and acini wherein there is nothing more than a slight desquamating epithelial hyperplasia. Other people consider the accumulations of lymphocytes which are observed at some parts of a growing carcinomatous edge to be further indications of a local attempt to limit the disease. There are so many parts of the growing edge at which there are no lymphocytes that it is hardly fair to Nature to believe her capable of exerting so feeble a defence. Again, upon *post-mortem* examination of a patient who had suffered from advanced mammary carcinoma I discovered small unsuspected supraclavicular lymphatic glands, which contained vigorous-looking epithelial cells which must have been lying dormant for a considerable time. There was no local reaction of any kind round these cells, although the disease must have been growing with intense rapidity in the liver of the person at the same time. This observation demonstrates two points: (1) that where the disease was lying dormant there was no visible reaction to account for the stagnation of growth, and (2) that there was probably systemic

influence in operation to arrest the growth of the epithelial cells in the supraclavicular lymphatic glands and to allow or encourage the intensely rapid growth in the liver.

There is another factor that I consider important, although at first sight it appears to be merely accidental. It is this: it seems to me important to separate in one's mind those factors which induce carcinoma from those intrinsic and extrinsic cellular operations that occur in a cell dividing into two cells. For example, there can be no doubt that tar and even x-rays can induce carcinoma, that the filthiness of the Ross tumour can induce one of four varieties of sarcoma, and that the entrance of a spermatozoon into an ovum initiates a propagation of species, yet we are perfectly ignorant of the intrinsic invisible factors that are operating in the cells, nor do we yet understand how they are influenced by variations in evolution, biochemistry, internal secretions, and so forth, operating upon them from outside.

In considering the induction of carcinoma one factor remains of paramount importance—the irritant must be applied directly to the actual cells which are eventually parents of the subsequent carcinoma, and the irritant is the main factor in the localization of the future disease. There must be also a time factor in the process of carcinoma. Experimentally the length of time carcinoma takes to appear seems to depend upon the intensity of the tar application. If tar be applied only once a week the period at which the carcinoma develops in mice is within about ten to twelve months. If it be applied twice a week or oftener the time can be reduced to four to nine months or less. There is a time factor even in intensive application of tar. The time factor may have an important bearing in giving time for preneoplastic epithelial hyperplasia in the ducts and acini of the breast, to which I have already drawn your attention. In addition to the visible effects in carcinoma there are some very cogent reasons for believing that there is a systemic invisible action or inhibition of action associated with the induction of carcinoma.

I pass on to adduce the evidence there is of a systemic influence upon the process of carcinoma.

(a) I have already indicated one, to which I do not again refer.

(b) It is perfectly well known that metastatic deposits in subcutaneous tissue in carcinoma of the breast may remain latent and show no signs either of their presence or activity for a period of thirty years after removal of the breast, then with almost dramatic suddenness a cancer en cuirasse develops covering the chest. Here is an indication of a systemic influence arresting carcinoma, and also of an influence which induces its subsequent intensely rapid growth. It is impossible to state whether the influences are different or whether they are due to modification of the same one.

(c) Primary carcinoma appearing in the same person at the same time in two different viscera, or on the skin and viscera, is a rare occurrence. The fact of its rarity suggests that the existence of a primary carcinoma protects a patient from the incidence of a primary carcinoma elsewhere in the body. In Great Britain most women who die of carcinoma are attacked either in their breasts or uteri. Yet it is extraordinarily rare for primary carcinoma of the breast to be complicated by a primary carcinoma of the uterus, and vice versa. It makes one wonder whether the incidence of a primary carcinoma in the breast protects a woman from a primary carcinoma in the uterus, and vice versa. In Holland carcinoma of the breast and uterus in females is not so common as in Great Britain. The females of Holland suffer more from carcinoma of the alimentary tract. Does primary carcinoma arising in these situations protect the women of Holland from primary carcinoma of the breast and uterus? Upon this point another factor must be taken into consideration.

While granting that these examples are indications of protection, there may be an explanation for the different sites of primary carcinoma of women in the two countries mentioned. It must also be granted that different sources of irritation may select different viscera for residual purposes. For instance, the nematode worm *Gongylonema neoplasticum*

Fibiger selects the stomach, another nematode worm *Trichosomoides crassicauda* Lowenstein selects the urinary bladder. The result of selection of different viscera by different agents of irritation, even though they belong to the same species, would explain the different viscera affected in the women of Great Britain and Holland respectively and collectively.

(d) There are indications that the removal of that part of an area in which carcinoma has appeared in a tar-painted area induces a later appearance of primary carcinoma in another apparently non-cancerous part in the same area (Murray). This experiment supports the assumption that the presence of one primary carcinoma may prevent or delay the appearance of another primary carcinoma.

(e) The fact that only a proportion of mice subjected to the action of tar develop carcinoma also indicates the existence of normal local or systemic protection.

(f) When carcinoma has developed and has been removed from one tar-painted area, it requires a more intense application of tar to induce a primary carcinoma in another area of the same mouse (Murray).

(g) The same difficulty in inducing carcinoma in a tar-painted area is experienced when the mouse under experiment has had a mammary carcinoma previously removed by operation (Murray).

(h) The work of Dr. Cutlibert Dukes especially conclusively proves that multiple adenomatous papillomata of the colon invariably end in carcinoma, yet only one or two, and occasionally three, among them become the site of primary carcinoma. Why is it that so few become carcinomatous unless the presence of one primary carcinoma protects from the incidence of another? When a primary carcinoma has appeared in two or three separate colonic adenomatous papillomata it may be that primary carcinoma appeared in them either at the same time or before the acquisition of immunity.

(i) Dr. Cramer excised and minced up the spleens from a number of mice and returned each to the peritoneal cavity of its own mouse. Tar carcinoma appeared much earlier in these mice compared with otherwise untreated animals.

[I pass on to another problem—namely, whether the removal of a primary benign tumour makes any difference to the rate of growth of secondary benign tumours of the same nature. I cannot verify the statement, but it is said by clinical observers that the removal of an intra-cystic papillomatous state in an ovary will induce the disappearance of secondary papillomata scattered over the peritoneal cavity. There is an observation of my own which bears upon this point. Small microscopic multiple fibro-adenomata in the breast occur more commonly than is generally supposed in the area of the breast immediately surrounding an obvious clinical fibro-adenoma. Yet it is rather rare, but by no means impossible, to discover a case in which the removal of a clinically obvious fibro-adenoma has been followed at a later period by the appearance of another fibro-adenoma in or near the same situation. All that can be said now upon this point is that either the removal of the obvious fibro-adenoma has no effect on its microscopical neighbour, or if there be one it is certainly not one that intensifies growth. I must say that at the present moment it is a hazardous speculation only, and much more investigation is required in this direction. Yet it may be that the effect of removal of benign tumours upon secondary foci of the same tumours may be different from the effect of the removal of malignant primary tumours upon secondary primary tumours.]

(j) Several years ago I drew particular attention to an influence—for want of a better term—a "trophic influence"—of the nervous system upon epithelial structures, and I pointed out that in some examples where hairs become grey on the result of advancing age, grey patches appear upon the maximum points described by Sir Henry Head in his work upon herpes zoster. These are points at which nerves become cutaneous. I have seen beards becoming grey on four symmetrical points—namely, where the mental and great auricular nerves become cutaneous on the face. Moreover, I showed that the mental nerve areas described by Dr. Head were completely white when the rest of the beard was only scattered with a few grey hairs. In

continuation of this demonstration I pointed out that if a diagram were made of all patients suffering from small rodent ulcers of the back their points of instance would coincide with those points on which the posterior spinal branches of intercostal nerves become cutaneous. In this respect they resemble early patches of leucodermia and scleroderma of the back. Further, I published examples in which the areas occupied by extensive rodent ulcers are sometimes identical with the distribution of nerves. I also showed some examples in which the spread of a rodent ulcer was arrested at the edge of the areas which had lost their tactile and thermal sensations. Dr. Cramer of the Imperial Cancer Research Fund, London in the *British Journal of Experimental Pathology* (vol. 6 p. 21) published a paper upon "Innervation as a factor in the experimental production of cancer," in which he said his experimental observations were in agreement with my clinical observations. His conclusion was as follows:

Loss of nervous control in an area of skin does not predispose to cancer on the contrary the presence of a peripheral sensory mechanism is an essential factor in the process of chronic irritation which leads to the development of cancer.

I would not dwell so much on this clinical observation of mine but for the fact that it has, after twenty-five years, begun to attract attention. Cramer and Oertel, for instance, have lately drawn some attention to it. I do not want it to be understood that the distribution of rodent ulcer alone occasionally occupies definite nerve areas, because I have examples where infective processes such as erysipelas, tuberculosis, and tertiary syphilis are also occasionally delimited at the margins of nerve areas. I have no doubt that there is a mutual affinity between nerve areas and infective processes which occasionally can be demonstrated clinically as well as in rodent ulcers. The anastomosis of blood vessels and lymphatic vessels at these margins is so complete that these vessels cannot influence the limitation of which I have spoken. Moreover, microscopic sections made of these margins show no mechanical obstruction to spread of disease.

(f) Miss Maud Slye considers that heredity plays the most important part in the incidence and genesis of disease.

Finally I refer to some recent contemporary notions concerning carcinoma. (a) Gye's conception of the genesis of carcinoma is that it is induced by the combined action of an ultra-microscopic virus and a specific factor. His conception has caused a great deal of controversy, and most observers have failed to confirm beyond any possibility of doubt the presence of two agents even when they repeat Gye's technique and experiments. Even if Gye were right in his conception, there are many points in the problem of carcinoma it would not touch, mainly those intrinsic and extrinsic cellular influences to which I have already alluded. I do not suppose for a moment that Gye would explain the evolution of an ape into a man by saying it was connected with the union of an ultra-microscopic virus and a specific factor. (b) Blumenthal associates a bacillus with the induction of malignant disease. Fibiger connects a nematode worm with rat carcinoma and Borrel discovered a filarial worm in the breast carcinoma of mice. Other observers have associated with carcinoma bilharzias, *Trichina spiralis*, the embedded head of a tapeworm, and hosts of other living agents.

After taking into consideration all these points it still has to be admitted that knowledge does not yet permit any definite statement to be made in answer to the question whether the incidence of carcinoma is induced by a living or lifeless agent, or both. Should a living agent be a factor, then the establishment beyond all doubt of the existence or non-existence of ultra-microscopic organisms will be more essential than ever. All the living and lifeless agents that have been described in association with carcinoma may be contaminated by the presence of these organisms. The complete establishment of the existence will upset a great deal of present bacteriological knowledge.

Do carcinoma cells differ specifically from any other cells? Warburg says that they do, and his work on the biochemistry of malignant cells enables him to state that under aerobic and anaerobic conditions they split glucose

into lactic acid and thereby differ from normal cells except retinal cells. This is the only biochemical difference that is known between normal (except retinal cells) and malignant cells. Warburg also states that the blood of the veins leaving the malignant tumour contains more lactic acid than the blood in the arteries supplying it. The excess of lactic acid in the veins leaving the tumour disappears when the blood reaches the general circulation; therefore examinations of the blood for an excess of lactic acid is of no value for purposes of diagnosis. Since Warburg's work it has been discovered that regenerating tissues can in aerobic and anaerobic conditions break up glucose into lactic acid, but the amount of lactic acid is relatively much less than in malignant disease. On the basis of his work Warburg suggests a hypothesis accounting for tumour origin. He conceives that normal tissues are not homogeneous but consist of a mosaic of cells growing and surviving by oxidation process of carbohydrate, interspersed with isolated cells which have a dual capacity of using either the carbohydrate oxidized process or the splitting process into lactic acid. In spite of the immense labour of Warburg and the wonderfully accurate and careful experiments he has conducted, the question still remains not very satisfactorily answered—whether normal cells can, after a time, develop the peculiar metabolism of carcinoma cells when the life of normal cells grows under conditions which impair their normal metabolism. Even if it be demonstrated that Warburg is completely right, that there are normal cells which from the moment of their existence can break up glucose into lactic acid "it does not explain why cancer cells grow" (W. Cramer).

In carcinoma there is another outstanding morphological fact that may have a biological significance. No nerve endings can be discovered in carcinoma. Although Horst Oertel has issued a preliminary report on "Innervation and tumour growth" (*Canadian Medical Association Journal*, 1928, xvi), in which he says he has been able to stain nerve fibres among carcinoma cells. I think it would be wiser to wait to hear what Oertel says in his final communications. Great care will have to be exercised in excluding the possibility that the nerves seen in malignant tumours are due to the presence of pre-existing nerve fibres among which the invading tumours have spread.

Finally, it may be asked, Why is there so much sterility of definite statement when the attention of scientific observers throughout the world is being devoted to carcinoma? The answer to this question can be only, that the problem will never be solved completely until we know what life is.

SOME OBSERVATIONS ON THE DICK TEST

BY

B. A. PETERS, M.D., B.C., D.P.H. CANAD.
MEDICAL OFFICER IN CHARGE HAM GREEN HOSPITAL AND SANATORIUM
BRISTOL LECTURER IN FEVERS UNIVERSITY OF BRISTOL

AND

S. F. ALFISON, M.B., CH.B. EDIN., D.P.H. CANAD.,
FIRST ASSISTANT MEDICAL OFFICER HAM GREEN HOSPITAL AND
SANATORIUM BRISTOL

The investigation here recorded was primarily undertaken to determine if there was any difference in the reaction to the Dick test in the fourth week of scarlet fever between cases with septic complications such as rhinitis and uncomplicated cases. We found in 48 septic cases that 21 (44 per cent) remained Dick-positive, and of 103 clean cases 31 were positive. The preponderance of positives was only noted in the cases with rhinitis and "spotty" faces.

The septic patients were given scarlet fever prophylactic vaccine in doses of 0.1 to 0.3 c.c.m. but, except in the case of rhinitis, the effects were not favourable. In rhinitis, the administration of an antientarrhal or even a simple staphylococcal vaccine will often bring about improvement, so that the effect is possibly not specific.

Four patients under observation, who had had definite initial attacks, showed relapses in the following circumstances. One who was convalescent had a definite relapse the day after a test dose, giving at the same time a positive test, on retesting him, fourteen days after the

acute stage of the relapse, he was still strongly positive. A second patient had a relapse nine days after giving a positive test. In another convalescent Dick-positive patient with rhinitis, relapse followed the injection of 0.1 c.c.m. prophylactic (=250 skin doses). The fourth patient, who was strongly positive during the acute stage, relapsed nineteen days later after a fourteen days' apyrexial period. A fortnight after this second attack he was still strongly positive.

Since two of these patients remained positive after two attacks of scarlet fever, and such a high proportion of convalescents were giving positive reactions, we decided to extend our investigation. We treated 194 convalescents in the fourth week of the infection, and found that 61 (31 per cent) remained positive. As a control we tested 116 diphtheria convalescents and found 48 positives (41 per cent).

The next group examined was 131 patients with scarlet fever in the first three days of the disease while still febrile and showing a rash. We found that a positive reaction could easily be read, even when a rash was present, because the scarlet fever rash affects only the papillae of the skin, giving the punctate appearance, while a positive Dick test causes a generalized erythematous patch. Many positive cases showed up brilliantly, even in a profuse rash. Here we found 64 positives and 67 negatives—that is, 49 per cent positives. We retested 59 of these in the fourth week, all those giving an initial negative test remained negative (20 cases). Of the initial positives (39 cases) 24 remained positive and 15 became negative, 5 patients in this latter group had had antitoxic serum. We did not observe any clinical difference in the course of the disease between those giving positive or negative initial tests.

Another group reviewed was composed of newcomers to our staff during the previous twenty months, 94 were tested and 33 were found positive (36 per cent). Fifteen of the staff tested gave a previous history of scarlet fever, and in 5 (28 per cent) of these the result was positive. This proportion does not differ materially from that obtained among those who had no history of a former attack. Seventeen of these patients were given 0.1, 0.2, and 0.5 c.c.m. doses of the prophylactic (1 c.c.m. = 2,500 skin test doses) and retested. Eleven of them were negative and 6 still remained positive. These became negative after two further doses of 1.0 c.c.m. One of the patients who received three doses developed scarlet fever six months later and after being tested again gave a strong positive reaction. She also gave a history of a mild attack of scarlet fever six years previously.

In recording the results of repeated test doses during scarlet fever convalescence one great fallacy has to be recognized—namely, that many persons with positive reactions may be easily converted into negative reactors by the small amount of toxin introduced into the skin by the test. To prove this point we gave repeated single skin test doses to eleven members of our staff who had given strong positive reactions on the first test. The results were as follows: one became negative after a single skin test dose, three after two doses, one after four doses, two after five doses, one after six doses, one after seven doses, while two who reacted as very strong positives to the first dose remained positive after seven doses.

Since it seemed possible that these negative results might be due to a local tissue immunity, some of those who became negative were tested on the skin of the leg. The results proved the immunity to be general, and not local.

All the staff while being immunized were employed in our sanatorium, which is a quite separate institution, so that there was no possible chance of their gaining immunity by small doses of infection apart from the injections. One nurse rendered negative by this latter method developed scarlet fever three months later, she was then found to be positive again. The attack was a very mild one, but was complicated by the onset of rheumatism and endocarditis. Tested in the third week of disease she was again negative. No nurse who was originally Dick-negative has contracted scarlet fever up to the present.*

* Since writing one Dick-negative reactor has contracted scarlet fever. She was tested seven months ago. On testing again the first day of her illness she was still negative.

Before discussing the interpretation of these unexpected results, the effects of scarlet fever antitoxin treatment in our wards may be recorded. Out of 960 admissions 114 of the worst cases have been given doses of scarlet fever antitoxin in amounts of 10 to 40 c.c., according to our estimate of the severity and duration of the disease. In 96 of these the results have been extremely favourable. In this group we have observed rapid decrease in the fever, clearing of the throat, cessation of purulent nasal discharge, and a low incidence of septic complications, such as otorrhoea (7 per cent.), in view of the fact that all the cases are severe ones. We have found antitoxin effective even so late as the fifth day of disease in septic cases. Only 3 deaths occurred out of a total of 960 cases, compared with 15 in the immediately preceding cases of the same number, none of whom received serum.

One of the fatal cases was a patient with the malignant haemorrhagic type of infection, who died a few hours following admission, after thirty-six hours' illness, 2 died of septic pneumonia. In these 3 cases the serum had no appreciable effect. In 15 others the disease was not influenced by serum. One of these was a second day case, 6 were third-day cases, 2 were fourth-day cases, and 6 fifth-day and after.

These failures are difficult to explain, since the patients appeared no worse than others with equal duration of disease who were strikingly benefited. For many years we have used galil with good effect in cases of scarlet fever with phagedenic ulceration of the throat, in some of these serum failures it was used with benefit. As this drug is no longer procurable in England we have recently tried sulpharazonobenzene (three different brands), but it does not appear to be nearly so effective.

One complication that appeared in 20 per cent of the serum treated cases was severe secondary cervical adenitis, although only one of these cases eventually suppurred.

DISCUSSION

In our results the most striking feature is the remarkably slight difference among the proportions of positives in the various groups. 31 per cent in the scarlet fever convalescents, 34 per cent in the staff group, and 41 per cent in the diphtheria convalescents. The surprisingly high proportion of negatives in the acute stage of scarlet fever was also quite unexpected (51 per cent). The fact that all the negative cases in the group remained negative and most of the positive cases positive on retesting strongly confirms our opinion that there was no error in observation.

Although some of the acute scarlet fever cases showed a reversal of reaction from positive to negative on retesting during convalescence more than half still remained positive. While our results on retesting in convalescence differ from those of many other observers who have retested scarlet fever cases repeatedly during convalescence, we think that others have not sufficiently recognized the powerful effect of a few repeated skin tests in producing immunity against the toxin in certain individuals.

Although four of the Dick-positive convalescents had second attacks of scarlet fever within a month clinical experience proves that the bulk of these persistently positive reactors are unlikely to contract scarlet fever again. It may be that the nose and pharynx acquire local immunity, although general antitoxic immunity is not developed.

We first thought the test material was at fault, but this cannot be the reason, because, if it had been too weak, while the number of positive reactions in convalescence would have diminished, the number of negative reactions in the acute stage would have increased. If strong enough to make all the acute cases positive it would presumably also have increased the number of positive reactions in convalescence.

Another curious fact in the etiology of scarlet fever is the rarity of attacks of scarlet fever in infancy, many observers have stated that this is indicated also by infants always being Dick (as Schick) negative. It has been too hastily assumed that this result is due to a passive immunity inherited from the mother. This view cannot be accepted in all cases, because we have frequently seen a nursing mother contract scarlet fever while her baby

escaped. Two such instances occurred in our present series of cases. In one instance the 8-day-old infant of a woman with definite scarlet fever, contracted the day after parturition, was tested and found Dick-negative. She escaped infection, although in a scarlet fever ward, while her mother was actually suffering from the disease, it is obvious that an infant cannot inherit what her mother does not possess.

Recently Dr Fletcher¹ has stated that in the Dutch East Indies, where scarlet fever does not occur, the bulk of young children give positive Dick reactions. With increasing age the number of negatives becomes equal to that found in countries where scarlet fever is endemic, thus an immunity is obtained in spite of the absence of scarlet fever.

We would suggest that immunity to scarlet fever is partly inborn or hereditary and partly a function of age, being high in infancy, rapidly decreasing in early childhood, rising again in later childhood and becoming comparatively high in adult life. It would appear that in any age group outside infancy reactors to the Dick test might be placed in three groups: those who are persistently strongly negative, those who fluctuate between positive and negative, and those who are strongly positive and, though convertible into the negative by artificial means, tend soon to become positive again.

We do not think the doctrine of immunity increasing in age, due to subminimal doses of infection through life, will cover all the recognized facts, especially the immunity of infants.

If it were not for the strikingly beneficial results of streptococcal antitoxin in 90 per cent of the cases we could feel doubtful of the etiological relationship of *Streptococcus scarlatinae* to scarlet fever, but even here there are some inexplicable complete failures. Moreover, although this serum reduces the fever within forty-eight hours by several degrees in most cases, in many it does not appear to extinguish it completely, as the temperature tends to hover between 99° and 100° F. for three or four further days.

Another interesting feature is that serum does not appear to prevent secondary cervical adenitis—that is, adenitis after the throat is apparently normal. This phenomenon does not commonly occur in other streptococcal throat infections, although in scarlet fever it is certainly common even after the mildest cases. These facts, coupled with our experience of the beneficial effect of galil (one of the arsenicals) where serum has failed, suggest the possibility that there may be another symbiotic factor, at present unknown, which might explain much that is inexplicable in the recent discoveries concerning the etiology of scarlet fever.

THE ANTIRACHITIC ACTION OF IRRADIATED ERGOSTEROL IN CHILDREN AND ADOLESCENTS

BY

S. J. COWELL, M.R.C.P.
(From the Royal Infirmary, Sheffield.)

It is now ten years since rickets was first proved by scientific experiment to be intimately related to the absence from the dietary of a specific food factor. This new conception of the etiology of the disease met with considerable opposition, but it has held its own against all previously recognized hypotheses, and to-day there are grounds for believing that the specific antirachitic food factor has actually been isolated as a pure chemical substance. The story of the experimental work that led from the original proof of the existence of the antirachitic factor to its isolation is a long but fascinating one, and the main steps in the chain of discovery may be condensed as follows.

To McLean¹ belongs the credit of establishing the existence of the antirachitic factor by means of his exhaustive investigations on puppies. He demonstrated that

rickets could be produced with certainty, and be prevented or cured with equal certainty, by the omission from, or addition to, the diet of certain foodstuffs, the most important of which were cod-liver oil, egg-yolk, cream, and butter. These foodstuffs, which he found were able to prevent the occurrence of rickets when given to growing animals, were known to be rich sources of the then comparatively recently discovered fat-soluble vitamin, or vitamin A. For some years it remained doubtful whether this growth-promoting vitamin A and the antirachitic vitamin were identical bodies, but in 1922 McCollum and his co-workers⁷ proved that they were two distinct entities, one of which (vitamin A) was more easily destroyed by oxidation than the other.

Many attempts were made to isolate these factors, and though it was found possible to obtain highly concentrated active fractions from such substances as cod-liver oil which were rich in fat-soluble vitamins, efforts to separate the vitamins as pure chemical substances were never successful.

In the meantime Hulsehinsky⁸ had demonstrated that rickets could be cured in children by exposing them to ultra-violet light. Shortly afterwards it was found by Hume,⁴ and by Goldblatt and Soames,² that rats kept without a supply of fat-soluble vitamin would grow better if they were exposed to ultra-violet light. Hume and Smith⁶ later found that stimulation of growth and good bone calcification occurred in rats as the result of exposing the cages in which they were housed to ultra-violet light, it was subsequently found that this occurred only when sawdust was present in the cages during the irradiation, some of the sawdust being afterwards eaten by the animals. Steenbock and Black⁹ were working at this time on the effects of ultra-violet irradiation, and they had already found that the irradiation of common foodstuffs previously devoid of any fat-soluble vitamins conferred on them the property of promoting growth and good bone calcification.

It seemed important to determine whether these findings were applicable to cases of human rickets, and in 1925 Cowell⁵ showed that active rickets could be cured in children by giving them milk which had previously been irradiated. Hess shortly afterwards published similar results obtained with dried milk, the same worker later found that the irradiation of apparently pure cholesterol rendered it powerfully antirachitic both in animals and children. For a short time it was believed that irradiated cholesterol might prove to be the much sought after antirachitic vitamin. It was soon proved that perfectly pure cholesterol could not be made antirachitic by irradiation, and in 1927 Rosenheim and Webster,⁸ and Windus and Hess,¹⁰ showed that the irradiation of the chemically related ergosterol converted it into an intensely potent antirachitic agent. It is now considered highly probable that this sterol is the true parent substance of the antirachitic vitamin, or "provitamin," and is converted into the actual antirachitic vitamin under the influence of ultra-violet light.

Irradiated ergosterol was shown to have a marked curative effect in clinical cases of rickets, and commercial preparations have been put on the market by reputable firms both in this country and in Germany. The German preparation is sold under the trade name of "vigantol", numerous articles have been published in Continental medical journals during the past few months describing the successful results obtained by its use in cases of rickets and osteomalacia. Three widely advertised British preparations are sold by the British Drug Houses under the names of (1) radiostol, which contains the antirachitic vitamin alone, (2) radiostoleum, which contains vitamin A as well as the antirachitic vitamin, (3) radiomalt, which contains both vitamins, together with malt. Few reports as to the efficacy of these preparations in clinical cases have yet been published. Aidin¹¹ has recently recorded a series of five cases of rickets in young children treated successfully by radiostol. The dose given to his patients was at first 3 minims three times a day, this was found to be insufficient to bring about rapid healing, and the amount was increased to 10 minims three times a day.

The cases of rickets about to be described were treated with the commercial preparations of irradiated ergosterol under controlled conditions in hospital. The diagnosis of active rickets was confirmed in every case by means of radiograms, and progress was followed by a series of x-ray photographs taken at frequent intervals. The patients' diets were chosen in such a way as to exclude the possibility of any considerable amount of antirachitic vitamin being consumed—that is to say, they were given but a small daily allowance of milk, no eggs, and no butter, they were allowed green vegetables, which furnished a supply of vitamin A. The patients themselves were kept in such positions in the wards that direct sunlight could not fall on them. It has previously been shown that under these conditions no appreciable healing of active rickets takes place in the course of a few weeks.

Case 1—A girl, aged 13 years, with marked deformities of the lower limbs and bronchial and nasal catarrh. Treatment: For the first twenty days 3 minims of radiostol were given twice a day, subsequently 5 minims three times a day. Slight healing at the epiphyses was noted after three weeks, and rapid healing after four weeks; healing was virtually complete in six weeks. After ten days in hospital she developed acute bronchitis, her allowance of milk was at once increased to 1½ pints a day and she became afebrile in three days. She gained 4 lb in weight during the six weeks of treatment.

Case 2—A boy aged 5 with marked rickety deformities. Treatment: For the first twenty days 4 minims of radiostol twice a day, subsequently 5 minims three times a day. Pronounced healing was apparent in three weeks; very dense calcification at the ends of the diaphyses in six weeks, though the margins were still irregular. He gained 4½ lb in the course of the treatment.

Case 3—A girl, aged 2, with moderate deformities of the lower limbs, florid rickets radiographically. Treatment: 5 minims of radiostoleum three times a day. Pronounced healing was apparent in three weeks, and healing was complete by the sixth week. Her general condition was much improved and she gained 1½ lb during the six weeks.

Case 4—A girl aged 13 with late rickets, she had noticed pain in her knees and slight knock-knee deformity for about two months, active rickets was clearly shown in the x-ray photographs. Treatment: 5 minims of radiostol three times a day. Healing was just beginning after ten days, and was practically complete in five weeks.

Case 5—A girl aged 17, with late rickets. She was small and underdeveloped for her age, she began to menstruate at the age of 16. When she was 15 she first noticed that she was getting knock-knees for two or three months before admission she had had considerable pain in her knees. Treatment: 5 minims of radiostol three times a day. Healing was just beginning after ten days, it proceeded rapidly after three weeks, and was almost complete in five weeks.

These cases show that the commercial preparations of irradiated ergosterol employed will bring about the healing of active rickets in young children of various ages and in adolescents. The minimal effective dose for bringing about rapid healing was approximately determined in Case 1, where 6 minims of radiostol a day produced only very slight healing in three weeks, whereas the later cases healed very rapidly in this space of time with 15 minims a day. It would appear probable that 15 minims of either radiostol or radiostoleum is a sufficient daily dose for most cases of rickets. It is unlikely that any ill effects would follow the giving of even considerably larger doses, though Kreitmar and Moll¹² have recently shown that certain experimental animals can be poisoned in a few weeks by giving them daily doses of irradiated ergosterol of the order of 1,000 times the minimal effective antirachitic dose.

It may perhaps be emphasized that though irradiated ergosterol will bring about the healing of rickets it does not, like cod-liver oil, contain vitamin A, and evidence is now accumulating to show that an adequate supply of this vitamin is all-important to secure resistance to infections. When, therefore, any preparation of irradiated ergosterol is employed as an antirachitic agent, it is essential to see that a sufficient supply of vitamin A is given at the same time. This can be done by including egg-yolk, butter, milk, and green vegetables in the diet, or by using a preparation which contains this vitamin in a concentrated form. All the young children whose cases are reported here put on weight during their treatment. Curiously enough the one that gained least weight was the one that received the extra supply of vitamin A, in the form of radiostoleum.

This work was assisted by a grant from the Medical Research Council to whom my thanks are due. I wish to express my thanks to Professor Mellanby for permission to publish these cases, which were under his care at the Royal Infirmary, Sheffield.

REPORT ON THE RESULTS OF EXAMINATION OF NINE CASES AFTER THE ORAL INGESTION OF 1,000 GRAMS OF GLUCOSE

BY

WALTER J. MAY, M.D. GLAS., M.R.C.P. LD.,
CONSULTING PHYSICIAN TO THE NATAL MENTAL HOSPITAL,
PIETERMARITZBURG

It has been stated by different authorities that it is impossible to make a normal person pass sugar in the urine after the oral ingestion of glucose.

The leak point of the kidney for glucose is now generally recognized as being between 0.16 and 0.18 per cent. MacLean¹ states that the hyperglycaemia resulting from the ingestion of carbohydrates appears in the normal individual, to be limited to about this level, the threshold level for glucose and cannot easily if at all be forced above it. He also goes on to state that in this fact lies the explanation of the difficulty in provoking glycosuria in the normal individual by giving glucose, a difficulty referred to in several recent publications. Later on in the same book he quotes Taylor, who, as the result of experimental work,² stated that "in the majority of healthy males there is no limit of assimilation of glucose, glycosuria does not occur following the largest possible ingestion of pure glucose." These observers in five instances gave doses of 500 grams of glucose, with the production of glycosuria in one case only.

Shapland,⁴ commenting on this subject, states that—

A striking phenomenon in the curve of the healthy subject is the intervention of the storage mechanism directly the blood sugar concentration approaches the normal renal threshold for sugar. This storage mechanism is so efficient that even if sugar ingestion is pushed to the limit of digestive tolerance it is rarely possible to produce a demonstrable glycosuria in a normal subject. It is indeed doubtful if alimentary glycosuria can occur in perfect health. Should it occur in a subject with a normal renal threshold for sugar it indicates a defect in dealing with excess of carbohydrate and therefore the patient should be regarded as a potential diabetic.

Up to the present all attempts at giving doses of more than 500 grams of glucose have failed, owing to the nausea and vomiting which were induced. It occurred to me that, as the native races of Natal are fond of sugar, it might be possible to induce them to take larger doses than those previously recorded. Acting on this assumption nine natives were examined. In each case an ordinary glucose tolerance curve was first done in order to eliminate any cases in which there might be any disturbance of the glycogen storing power of the liver. For this the usual dose of 50 grams of glucose was employed.

MacLean's method of estimating the blood sugar was employed throughout the investigation, and the urine tests were made with Benedict's solution. It will be seen from examination of the charts that, with the exception of Cases 3 and 5, a normal glucose tolerance was found. Cases 3 and 5 each showed a maximum blood sugar concentration of 200 mg. per 100 c.c. of blood. I think that it may be assumed that these two readings are within the limits of experimental error. Each patient was then given a dose of 1,000 grams of glucose, and in each case this huge dose was swallowed without any nausea or vomiting. Cases 1, 5, 6, 7, and 9 show a distinct rise in the blood sugar and a definite glycosuria. Examination of the charts will show that the glycosuria varied from a trace up to 2 per cent. The hyperglycaemia varied within rather wider limits.

This series of cases, though small, shows definitely that the ingestion of huge doses of glucose strains the glycogen-storing capacity of the liver to its fullest extent, and that there is then a certain degree of overflow.

During the course of this investigation I discussed these cases with Professor MacLean, who pointed out that in his opinion the interesting point was that some of the cases passed sugar in the urine with a blood sugar content which was lower than that which is ordinarily accepted as the minimal existing level. (See Cases 2, 3, 4, and 8.) It

In each of these charts the continuous curve shows blood sugar after 50 grams of glucose, the interrupted curve shows blood sugar after 1,000 grams of glucose.

Chart 1

Chart 2

Chart 3

Chart 1 (Case 1)—Urine after 50 grams of glucose: 1 hour nil; 2 hours nil. After 1,000 grams of glucose: 1 hour trace; 2 hours 1½ per cent.

Chart 2 (Case 2)—Urine after 50 grams of glucose: 1 hour nil; 2 hours nil. After 1,000 grams of glucose: 1 hour nil; 2 hours 1 per cent; 8 hours 2 per cent; 13 hours 1 per cent.

Chart 3 (Case 3)—Urine after 50 grams of glucose: 1 hour nil; 2 hours nil. After 1,000 grams of glucose: 1 hour nil; 2 hours trace; 14 hours trace; 20 hours trace.

Chart 4

Chart 5

Chart 6

Chart 4 (Case 4)—Urine after 50 grams of glucose: 1 hour nil; 2 hours nil. After 1,000 grams of glucose: 1 hour trace; 2 hours 1 per cent; 6 hours 1½ per cent; 18 hours 1 per cent.

Chart 5 (Case 5)—Urine after 50 grams of glucose: 1 hour nil; 2 hours nil; 3 hours nil. After 1,000 grams of glucose: 1 hour nil; 2 hours 1 per cent; 3 hours 2 per cent; 6 hours 2 per cent.

Chart 6 (Case 6)—Urine after 50 grams of glucose: 1 hour nil; 2 hours nil. After 1,000 grams of glucose: 1 hour trace; 2 hours 1 per cent; 6 hours 1½ per cent; 18 hours trace.

Chart 7

Chart 8

Chart 9

Chart 7 (Case 7)—Urine after 50 grams of glucose: 1 hour nil; 2 hours nil; 3 hours nil. After 1,000 grams of glucose: 1 hour nil; 2 hours trace; 3 hours 1 per cent.

Chart 8 (Case 8)—Urine after 50 grams of glucose: 0 hour nil; 1 hour nil; 2 hours nil. After 1,000 grams of glucose: 3 hours trace; 15 hours 1 per cent.

Chart 9 (Case 9)—Urine after 50 grams of glucose: 1 hour nil; 2 hours nil; 3 hours nil. After 1,000 grams of glucose: 1 hour nil; 2 hours 1 per cent; 7 hours trace.

was interesting also to note that in some cases the glycosuria persisted for periods up to eighteen hours after the ingestion of the glucose.

In view of the information derived from these experiments it is interesting to review again the current views on alimentary glycosuria and renal glycosuria. Cammidge³ admits that if the glycogenetic powers of the liver are exceeded a portion of the carbohydrate derived from the food may enter the peripheral circulation, and so produce hyperglycaemia and glycosuria. In this way, he states, it

is possible to account for the glycosuria produced by large doses of sugar, even in healthy people

Graham⁶ states that a study of the blood sugar in cases of so-called alimentary glycosuria and severe diabetes does not suggest that there is any difference between the two types. In both the machine which regulates the taking up of the sugar from the blood is only out of action to a greater or less extent, the tissues are unable to burn sugar, which therefore floods the blood and is excreted in the urine.

Commenting on this series of investigations, Professor MacLean suggested that in the cases where the normal renal threshold was not exceeded, but where glycosuria was found, there might be some mechanism which lowered the normal threshold in order to eliminate the excessive quantity of sugar ingested. Cases 2, 3, and 4, and possibly 8, show that it is not necessary to have hyperglycaemia before glucose is passed in the urine, while in Cases 1, 5, 6, 7, and 9 a hyperglycaemia as well as a glycosuria was demonstrated.

The investigation was carried out on natives in the Mental Hospital, Pietermaritzburg. It might be contended that these subjects were not normal. I maintain, however, that the normal glucose tolerance after 50 grams shown by the cases eliminates any possibility of there being any defective power of glucose storage due to their mental condition. I have come to the tentative conclusion that in normal persons there is present in the kidney a hypothetical mechanism which is brought into play when huge doses of glucose are given. By this mechanism the kidney can eliminate the excess of sugar in the urine without increasing the blood sugar content. If this is so then it would be possible to explain renal glycosuria as either an absence of this hypothetical mechanism or also as an impairment of it.

SUMMARY

Nine cases showing a normal glucose tolerance were examined after the administration of 1,000 grams of glucose.

Five of these cases showed a hyperglycaemia with a corresponding glycosuria. Four of the cases showed no hyperglycaemia, but showed a glycosuria varying from a trace to 2 per cent. Therefore, these cases passed sugar in the urine at a leak point which is below what is considered to be the leak point of the normal person. Seven of the cases continued to pass sugar in the urine for varying periods up to eighteen hours after the blood sugar had returned to normal limits.

I wish to thank Dr. Egerton Brown, superintendent of the Mental Hospital, for his courtesy and consideration during the investigation. J. D. Montgomery.

A NOTE ON ETHER CONVULSIONS

BY

A. C. REES WALTON, M.B. BIRM., M.R.C.S.,
THE CHILDREN'S HOSPITAL, BIRMINGHAM

IN view of the interest aroused recently in convulsions occurring during ether anaesthesia, the following case is recorded as one in which impurities in the ether were a causative factor in the condition.

A girl aged 8 years, was admitted to the Children's Hospital, Birmingham, on April 28th as a case of acute abdominal crisis. Careful inquiry failed to elicit any previous history of epilepsy either in the child or in the parents. On admission she presented a very toxic appearance and marked pyrexia although the symptoms were only of a few hours duration. Immediate laparotomy was performed at 11.30 p.m. No morphia was given before operation but atropine sulphate 1/100 grain was administered according to routine half an hour previous to it.

Operation.—Anaesthesia was induced by a mixture containing two parts of ether to one of chloroform and open ether sequence. The child passed quietly through the opening stages, and all

was proceeding comfortably until the intestines were handled. Although deeply anaesthetized she began to show distress indicated by jerky respiration and a slightly greyish tinge. Various measures were tried at this stage to combat the difficulty—namely, air breathing alone, deeper anaesthesia, and oxygen administration together with ether. As a result her colour improved and gradually the breathing became more regular so ether alone was resumed. In a short while twitching of both eyebrows occurred and the facial muscles next became involved, the eyeballs remained stationary with the pupils fixed and widely dilated. These myoclonic movements were rapid and continuous at the rate of approximately seven per second. In turn the left arm, abdominal muscles, trunk muscles, leg and right arm muscles were involved. The rate of twitching became less and the amplitude of movement increased. Until the skin sutures were inserted periods of generalized convulsions alternated with brief intervals of flaccidity. The jactitation of legs and abdomen was of sufficient magnitude to throw off instruments which were laid there and to interfere with peritoneal and muscular suture. Continuous oxygen through an airway—which latter had been used throughout—had no effect on the convulsive movements. The ether-chloroform mixture was also tried for about ten minutes during the later part of the operation, and this coincided with the onset of intermittent but more powerful convulsions.

Condition Found at Operation.—No free pus was found but there was hyperaemia of the lower abdominal peritoneum. The appendix was bound down to the posterior wall of the caecum, and therefore was not removed since the caecum could not be mobilized. A tube was left to drain the pelvis and later a sero-purulent discharge issued from which pneumococci were isolated in culture. The operation took approximately forty-five minutes. Convulsions persisted for about thirty minutes. The optic fundi examined at the close of the operation revealed no abnormality. Before leaving the operating table the patient showed profound exhaustion as a result of the continued convulsions, the pulse rate having risen from 140 to 160 per minute with a coincident marked fall in pulse volume.

Subsequent Progress.—After leaving the theatre at 12.15 a.m. the patient remained quiet for half an hour, a second series of convulsions then occurred. They were as before epileptiform and generalized in distribution. This time they lasted for twenty minutes being controlled by a small rectal dose of potassium bromide and chloral hydrate. After a free interval of twenty-five minutes she was again seized by an attack, lasting for twenty minutes during which time a further dose of potassium bromide and chloral was given. At 2.15 a.m. a fourth and last series of convulsions occurred after a free interval of twenty-five minutes. This time the spasms were of mild degree and confined to the right side. Consciousness was not regained in the usual manner afterwards but the patient had a restless night and was very dazed.

During the following twenty-four hours she only vomited twice. For forty-eight hours afterwards there was marked delirium and restlessness but, judging from the high temperature and pulse rate this might have been due to the virulence of the infecting organism. The patient has since made gradual but good progress towards recovery.

COMMENT

By a coincidence a short article on tests for ether impurities appeared in the *Lancet* of the same date as the above described case. E. B. Robinson¹ of Manchester University describes two tests as advocated by W. Wolbe². One is for the detection of acetaldehyde by means of an alkaline-ammoniacal solution of silver nitrate, the second test is for the presence of peroxides by means of a reagent consisting of potassium iodide and phenol phtalein.

I am indebted to Dr. Hickmans, biochemist to the Children's Hospital, who investigated samples of the ether administered in the above case, and nine other sample bottles from the same batch. The ether employed in the present case was a new bottle, which was only opened shortly before use, and had been kept in dark storage since it was received from the makers in April, 1928.

The nine other bottles, taken at random from stock, failed to respond to either test, whereas the bottle of ether used in operation gave a strongly positive reaction to the presence of acetaldehyde and peroxides. Moreover, when a small sample of ether from the implicated bottle was poured into the palm of the hand and allowed to evaporate, a noticeably pungent acid smell was noted, whereas the other samples merely left a clean, sweet, ether odour.

It is necessary, I think, to mention here that the first test solution is more unstable than hinted at by E. B. Robinson. When the reagent A (the alkaline solution of silver nitrate) and the tested ether mixed with it were poured away, on the day following the test, a violent explosion occurred in each case, a biochemist being temporarily disfigured by spots of black silver stain. If the solutions are poured away immediately after the conclusion of the test all is well.

CAUSES OF THEIR CONVULSIONS

Various factors have been presented as giving rise to the alarming and only too frequently fatal convulsions arising during ether anaesthesia.

1 *Impurities in the Ether*—This factor was strongly upheld by the late Dr S. R. Wilson.¹ He maintained that the convulsions were of toxic origin, and resulted from the action of acetaldehyde causing cell asphyxia by its inherent properties as a reducing agent, with the subsequent formation of acetic acid. That this was the cause in my own case I have no doubt. The convulsions gave every appearance of arising from severe and continuous irritation of the central nervous system. Evidently there was present some toxic product which was not eliminated from the system as rapidly as ether, hence the post-operative convulsions. Again in favour of a neuro-cell disorder was the subsidence of convulsions after the exhibition of bromides and chloral.

2 *Deep Etherization*—This has been suggested as a cause. In answer to this, it may be asked how many cases of ether convulsions have been observed in comparison with the number of cases that have been deeply etherized?

3 *Excess of CO₂ in the system* is suggested by Dr Pinson⁴ as a cause of dyspnoea, with exaggerated muscular activity overflowing from the respiratory group to the rest of the body. In the case recorded, at no stage of the operation was there any marked excess of CO₂. An airway was used throughout, and except for one short period the patient kept a good colour.

4 *Lack of oxygen supply to the brain*, due to oedema and collapse of the lung bases, is suggested by Dr Gwathey⁵ as a result of various animal experiments. Against this theory is the failure to arrest the convulsions in my own case by free ventilation of the patient with oxygen.

5 *Atropine overdosage* has been put forward by Dr Hornabrook.⁶ On the other hand, the dose administered in this case was the usual routine pre-operative measure adopted at this hospital, and no similar case had occurred before.

6 *Renal origin* has been suggested. In the present case the urine before operation was found to be free from pathological elements, but after operation ketone bodies were present in abundance. This latter finding is again in support of a toxic origin of the convulsions.

7 *Idiosyncrasy* has been offered as being the basic factor. Obviously this affords a very wide field for speculation, and only time will prove or disprove this theory.

8 *Various minor factors*, such as youth, pre-existing toxæmia, and heat, have been postulated. Cases are on record supporting and opposing these factors.

SUMMARY

A case of epileptiform convulsions is described occurring during the course of ether anaesthesia.

The ether was shown, by readily utilized tests, to contain large proportions of two well-known impurities sometimes associated with ether.

Although nine other bottles of the same batch were subjected to the same tests no impurities were detected in these.

Acetaldehyde was probably the factor causing the convulsions by its action on a nervous system perhaps already rendered susceptible by a pneumococcal septicaemia, but certainly a nervous system to which epilepsy was previously quite foreign.

Acetaldehyde, being of higher specific gravity and therefore less volatile than ether, accumulated in the system and was eliminated less speedily, thus causing the delayed post-operative seizures.

No cases of ether convulsions were recorded when ether was used as an anaesthetic during the seventy years previous to 1919. At this time various contentions were published that pure ether was not an anaesthetic, and as a result impure ethers came into use.

THE SYSTEMIC TREATMENT OF INFECTIVE ARTHRITIS

BY

VINCENT COATS, M.C., M.A., M.D. CANTAB.,
M.R.C.P. LOND.,

PHYSICIAN, ROYAL MINERAL WATER HOSPITAL, BATH

MARQUENADE of the condition formerly designated rheumatoid arthritis and, more recently, infective arthritis under the title of focal arthritis, together with the importance attached to the discovery of a focus of infection, has resulted in too narrow an outlook and oversight of the fact that, at any rate from the therapeutic point of view, this condition should be regarded as a systemic infection and not as a disease of joints.

This view, which of necessity embraces a wider outlook, calls for more comprehensive methods of treatment, the essentials of which are a raising of the individual's immunity and the correction of biochemical abnormalities—the former implying the principles of treatment commonly applied to the active stage of, say, tuberculosis and the latter, adjustment of departures from the normal in each system, the alimentary, the haemopoietic, etc. stage by stage. The success of such treatment depends in large measure upon individual experience in knowing just when to tackle each system. It will thus be seen that every case requires individual consideration in the matter of treatment section by section. Actual joint treatment will not be discussed in this paper.

The removal of infective foci, when present and obvious, should automatically take place, not necessarily in the hope of immediate results, but as a routine to relieve the individual from any embarrassing load factor.

Bearing in mind the common incidence of tonsillar and oral sepsis in non-arthritis it does not seem unreasonable to suggest that the alimentary tract, even in virtue of size and occultness alone, is potentially the source of infection in a large percentage of cases of arthritis and the not unusual methods of treatment by intestinal antiseptics, Plombières douches, and vaccines made from intestinal organisms are tacit witnesses to this view.

The relative value of any form of intestinal disinfection is difficult to assess correctly, in that some cases respond more readily to one treatment than others, and the chronicity of the disease bears a definite relationship to this response. I am rather in favour of the administration of small doses of calomel, such as one sixth of a grain every hour for six doses on alternate days, followed by a saline the next morning. Another method found most efficacious in some instances is that of changing the pH value of the intestinal medium by administration of pure cultures of lactic acid bacilli in milk twice a day. On some occasions the rectal administration of this has been tried after colon evacuation by enemata. Plombières douches have been found extremely useful on the whole and are always worth consideration. It is difficult to estimate the disinfecting powers of potassium permanganate in capsules when taken by the mouth and followed by a draught of water on an empty stomach, but this method with or without rectal irrigation with permanganate solution has its advocates. Guaiacol carbonate with sublimed sulphur in cachets over a long period of time is a routine of long standing. The administration of streptococcal vaccines would seem to be most indicated where there is an associated nasopharyngeal involvement especially when allergic in origin. In the atrophic form of arthritis achlorhydria is exceedingly common, and if the result of a fractional test meal proves this to be the case hydrochloric acid well diluted should be given at meal times.

Although in many cases of infective arthritis personally investigated the levulose tolerance test and Widal's haemolysis test seem to be too gross to demonstrate a liver inefficiency yet an hepatic inadequacy of a mild or moderate degree may be assumed on the summary of evidence obtained by a skilled biochemical opinion on the urine and stools, and the somewhat haphazard diet sometimes prescribed for these patients is capable of adjustment to meet the capabilities of any particular digestion until such time as the temporary rest afforded to the liver

Wobbe. *Chemisches Centralblatt* 1903, lxxiv, 458. ² Wilson. *Lancet*, May 20th 1927, p. 117. ³ Pinson. *British Medical Journal*, May 28th 1927, p. 537. ⁴ Gwathey. *Lancet*, June 25th 1927, p. 1358. ⁵ Hornabrook. *British Medical Journal*, September 10th 1927, p. 471.

by these means is no longer required. When the sugar storage mechanism is at fault and an emaciated patient is required to put on weight, insulin in suitable doses, together with the ingestion of glucose or sugar candy, has been found very useful.

Moderately severe secondary anaemia is usual in infective arthritis. This has to be combated by the methods usually adopted in secondary anaemia, such as iron and arsenic by the mouth or injections of serum ferrugineum, but it is not unusual in chronic cases to find a fatigued bone marrow, and recently liver feeding has produced some hopeful results. The troublesome leucopenia which follows prolonged arthritis sometimes responds to injections of nucleic acid.

The value of skilfully given massage as a general measure in infective arthritis is too well known to need comment, but hydrotherapy (though its indiscriminate use in the acute and subacute stages has brought discredit on many spas) is useful, when properly applied, throughout the course of the disease, quite apart from the question of joint treatment, as a general sedative or stimulant to metabolism, to induce sweating and ensure sleep. Moreover, any well equipped spa, being an arthritic unit in itself, implies the presence of specialized apparatus and personnel. In the systematic treatment of arthritis hydrotherapy is particularly useful in increasing the function of that highly specialized but much neglected organ the skin. The sweat in the grosser forms of arthritis has a characteristic and tenacious odour and the skin is apt to be either greasy and opaque or else atrophic and shiny, the various methods of hydrotherapy, therefore in overcoming the dysfunction of the skin cannot be overestimated. In arthritic cases complicated by fibrositis and more particularly by panniculitis there is no treatment which adequately takes the place of hydrotherapy.

PERSISTENT PRIAPISM DUE TO SECONDARY CARCINOMA IN THE CORPORA CAVERNOSA

BY

R. CAMPBELL BEGG, M.C., M.D., F.R.C.S. Ed.,
F.A.C.S., F.C.S.A.

SENIOR UROLOGIST, WELLINGTON HOSPITAL, NEW ZEALAND

SCHUEER,⁴ in an elaborate classification of the causes of priapism published in 1911, mentions as a subleading neoplastic diseases of the penis "This appears to be, however, a rare phenomenon, as is, indeed, priapism itself."

It seems worth while to record the following case in which the etiology of the symptom was not ascertained during life.

A labourer, aged 62, was admitted to my service in the Wellington Hospital on March 18th 1926 with the history that five weeks previously the penis had become erect and had remained so. There was mild aching pain about the organ at times shooting into the perineum and thighs. He had had mild nocturia for some years. Since the onset of the priapism there had been some scalding on micturition, but no difficulty and the stream was good. He stated that at times the urine was dark in colour. There was no definite haematuria. He had not lost weight or strength.

Examination showed him to be a well nourished somewhat adipose man. No oedema was present. The cardiac and respiratory systems were normal. Blood pressure 140/80. The abdomen was very large owing to fat and was difficult to palpate. There was no apparent enlargement of the liver or spleen, no dullness in the flanks, no pain on pressure in the costo vertebral angles. Neither kidney was palpable or tender. The testicles and scrotum appeared to be normal. The penis was erect, hard, and turgid, lying parallel to the abdominal wall. No irregularities were felt on careful palpation of the corpus spongiosum or corpora cavernosa.

On rectal examination a soft uniformly enlarged prostate gland was felt projecting markedly into the rectum and extending upwards so that the examining finger could barely reach the uppermost limit. No nodules or indurations were felt in the region of the bulb or membranous urethra.

The urine was acid, with no deposit, specific gravity 1018. No white cells, organisms or red cells were present.

A blood count showed red cells 4,500,000, white cells 7,000, lymphocytes 34 per cent. The central nervous system seemed normal.

The Wassermann test of blood and spinal fluid was negative. The Kahn test also was negative.

Kidney function: phthalin, 52 per cent in first two hours. Blood, non-protein nitrogen, 40 mg per 100 c.c.m. There was no residual urine. It was impossible to pass a cystoscope for study. Plain x-ray gave negative results.

Provisional Diagnosis—Leukaemia and central nervous disease having been eliminated the cause of the priapism remained obscure. The only notable pathological feature was the very large prostate.

All the usual non-surgical measures were tried without any effect.

Operation—Suprapubic prostatectomy was performed. The mass removed, comprising two lateral lobes, had the dimensions of 6 cm by 5 cm. Microscopically there was no sign of malignancy.

The patient seemed to recover well from the operation, but the priapism was little, if at all, improved. He was allowed up on the third day. On the eleventh day he was not so well, and there was very little urinary secretion. In spite of all treatment the urinary flow was not properly re-established. The non-protein blood nitrogen reached 67 mg and he died in coma on April 29th fourteen days following the operation.

Autopsy Findings—There was a suprapubic wound partially healed and a healthy looking prostatic cavity. The bladder showed no inflammation and but little trabeculation. The ureters were not dilated. The right kidney was normal in size but on section showed early dilatation of the pelvis and some toxic pallor of the cortex. The left kidney presented a cystic swelling on its upper and outer aspect. The cyst was lined by necrotic membrane and filled with blood-stained turbid fluid. It did not communicate with the pelvis, which was somewhat dilated. The kidney was pale and at one part of the cortex was a small whitish nodule of tumour. The liver was filled with discrete masses of new growth. The corpora cavernosa were infiltrated with white masses of tumour which in parts showed red patches of degeneration. The fibrous capsule was not invaded except on section there was no evidence of the growth. There was no glandular involvement and there were no other metastases.

Microscopical Appearance—The nodule in the kidney and the walls of the cystic cavity, together with sections of the deposit in the liver all gave a similar appearance—namely masses of cubical cells having an elongated anastomosing arrangement strongly resembling the convoluted tubules of the kidney. This is a not uncommon appearance in sections of certain portions of so-called Granitz tumours and is fairly characteristic of carcinoma as seen in the renal substance. Primary carcinoma in the corpora themselves would presumably not take on this formation but would be of the carcinoma simplex type with stroma more or less developed. For this reason it is assumed that the primary growth was renal. The late development of symptoms as associated with a lesion of the corpora would confirm this view.

Comment

The commonest causes of priapism of the persistent type appear to be leukaemia and lesions of the central nervous system. Cases in which it is due to blocking of the circulation in the corpora cavernosa by malignant growth are rare. Dr. Frank Hinman² published in the *Annals of Surgery* in 1914 a comprehensive review of the subject of priapism in general, and in 173 references in the bibliography attached not a single one was due to malignancy.

The only reference found in a casual survey of more recent literature was in a case reported by Cowie,¹ in which the substance of the corpora cavernosa was replaced by myxosarcomatous tissue spreading from a primary growth in the prostate.

Dr. W. A. Frontz of Baltimore recently reported a case at the annual meeting of the American Association of Genito-urinary Surgeons, Atlantic City, N. J. This case was not diagnosed until necropsy. An attempt was made to relieve the condition by incision into the corpora cavernosa. At necropsy extensive metastases were found, but Dr. Frontz was inclined to think that the tumour was primary in the corpora cavernosa. At the same meeting Dr. H. H. Young³ of Baltimore mentioned that he had encountered a similar case.

Diagnosis in these cases is apt to be erroneous as the growth is well confined in the sheath of the corpus and no nodulation can be felt from the outside. In cases where malignancy is widespread in other parts of the body no treatment appears to be of any use.

THE EIGHT STAGE CLASSIFICATION OF PULMONARY TUBERCULOSIS

BY

B. A. PIROTT, M.D. PETROGRAD, I. M. S. S. A. LONN,
CONSULTING PHYSICIAN TO THE RUSSIAN RED CROSS SOCIETY (OLD
ORGANIZATION) AND RELIEF FUND IN GREAT BRITAIN

THERE is no doubt that classification plays a very important part in the questions of regime, treatment, and prognosis of tuberculosis of the lungs. The more exact the diagnosis the more definite and the more successful may the result of treatment be. Not only is the stage of disease important, but even still more, in my opinion, is the tendency of the process—that is, the rapidity of the development of the disease and transition into the next stage. It reminds me of a non-stop train rapidly travelling towards its destination and passing all stations. The damage may only be noticed at the end of the journey, when it may be too late or too complicated to repair, or there may be a serious accident on the way, quite suddenly and unexpectedly. But if the train stopped at each station and was inspected and examined in every detail remedial measures might be undertaken and disaster be averted.

A brief classification is comparable with such a "non-stop" train, and is especially unsatisfactory for the inexperienced practitioner, since the most important part of the disease—the rapidity of development—may entirely escape attention. This is especially serious when the patient is sent to another medical consultant, because everything turns on two fundamental points—the exact stage of the disease and how quickly it developed. The rest depends upon the experience of the doctor and the condition in which the patient is and to which he could afterwards obtain. It is unnecessary to enumerate all the classifications, but some should be mentioned, especially the well-known and most imperfect Turban-Gerhard, where the third stage includes an immense quantity of variations under only one label.

Brehmer's classification resembles that of Turban in character, but combines all forms of pulmonary tuberculosis in three groups:

1. The acute form—as, for example, military tuberculosis.
2. The subacute and chronic forms including the caseous, caseo-fibrous and fibrous varieties.
3. Abortive forms such as that at the apex of the upper lobe.

A slightly more detailed classification was suggested by Dr. A. Sokolovsky of Poland (Wykłady kliniczne chorób dróg oddychowych). He also recognizes three stages, but subdivides them into more detailed forms:

A Chronic Tuberculosis

1. The early stage (a) With evident signs of lesion of the organs of respiration (b) With concealed signs (1) pseudo-chlorosis (2) pseudo-cardiac form (3) pseudo-malarial form (4) pseudo-gastro-intestinal form (5) pseudo-pleuritic form (6) pseudo-bronchial form, (7) pseudo-laryngeal form (8) pseudo-empysematous form.
2. Tuberculosis of lungs completely developed—stage of liquefaction and destruction.
3. The fibrous form.

B Acute Tuberculosis

1. Acute caseous tuberculosis (a) local (b) diffuse.

C Acute Military Tuberculosis

1. Typhoid form (septicæmie bacillaire tuberculeuse).
2. Acute tuberculosis (form asphyxique de la phthisie aiguë—Graves).

Sir Robert Philip bases a detailed classification on the degree of systemic intoxication recognizing that the toxæmia plays the great part in the course of the malady. Often the local changes are most extensive, but systemic intoxication is very slight, on the other hand, comparatively slight changes in the systemic disturbances in the lungs may be extremely serious. The prognosis in these cases depends upon what condition governs either the extension of the process or the systemic intoxication.

He adopts a symbol L to designate the local lesion of the lungs, and a symbol S for the systemic involvement, by combining capital and small letters it is possible to express the diagnosis with more or less accuracy. In addition, Sir Robert Philip uses the small numbers, 1, 2,

and 3 indicating the stages of Turban. For instance, L₁S means early local process with slight systemic intoxication, and L₂S the same early process but with more severe intoxication. Symbol 1 represents the relatively hopeless case, so, for instance, L₁1, L₂1, and L₃1 are the groups where the toxæmia is not in proportion to the extent and severity of the local lesion of the lungs.

His classification divides tuberculosis of the lung into two clinical groups. This classification is very detailed, but gives place to subjectivism because the degree of systemic toxæmia is less distinctively conceived than the extension of the lesion. Various observers may indicate the same degree of toxæmia differently, besides which, used as a basis in this way, the Turban classification is particularly exact.

I do not think it is necessary to describe the classifications proposed by Petruschky, Cornet, Rohden, Bencke, Laonus, Williams, Germain Sec, Hoffmann, Bard, Frankel Meissen, and others, none of these, in my opinion, give an exact definition of the stage of the process. This is why I propose the classification of Professor Gaborlovitch as the best one for obtaining this purpose and the most detailed and exact.

CLASSIFICATION OF PROFESSOR GABRILOVITCH

Gaborlovitch divided all forms into two groups (1) the primary, and (2) the secondary. Each of these groups he subdivided into four forms or stages.

The Primary Group

- 1 Sicca
- 2 Catarrhalis
- 3 Fibrosa
- 4 Ulcerosa

The Secondary Group

A Broncho-pneumonia metastatica chronica:

- 1 Fibrosa
- 2 Ulcerosa

B Pneumonia tuberculosa chronica

- 1 Fibrosa
- 2 Ulcerosa

For the basis of this classification was taken the pathologico-anatomical condition of the lungs and the clinical signs. Toxæmia plays a very important part in the "index prognosticus," but is not included in the classification. With regard to the general characteristics of this classification it is very expedient to divide tuberculosis into two groups—the primary and secondary—the latter being merely the consequences of the former.

The tuberculous process in the lungs extends chiefly in two ways. One of these is often the result of aspiration of particles of lung (especially after hæmoptysis) into the lower lobes, Gaborlovitch calls it "broncho-pneumonia metastatica chronica." The other way is infection spreading by continuity and gradually involving adjacent parts of the lungs—the so-called "pneumonia tuberculosa chronica." In the first case the middle lobe of the right lung is always found in good condition without any signs of inflammation, but the upper and lower lobes are affected. In the second case the area affected is only the continuation of the process from the neighbouring part of the lung.

Turban's classification gives no distinction between these two forms attributing them to the third stage only, but there is a very great difference between them, and, as a rule, the first is much the more dangerous, and is very grave as regards prognosis.

I will now describe the details and characteristics of all forms of this classification.

PRIMARY FORMS

1 Sicca—Thus, the initial form of the process, is distinguished from pathologico-anatomical standpoints by the formation of a very small fibrous nodule, partly undergoing caseous degeneration. Slight dullness at one or both apices may be present. Auscultation may reveal a weak inspiration or prolonged expiratory sound over the affected region. As a rule there are no complications. The healing process may consist in the formation of fibrous tissue, and, clinically, there may sometimes be found signs of the healed area, which is nearly the same, but not so distinct, as at the time of development. The capacity for work is undiminished.

2 Catarrhalis—This, pathologico-anatomically, means the transition of a fibrous nodule into caseous masses and the formation of exudative caseous foci. As a rule the upper lobe is affected, and some degree of dullness is present with bronchial breathing and crepitation. There are complications in approximately 15 per cent of the cases. Healing is due to the formation of fibrous tissue, which is interspersed also between the affected and sound parts of the lung. Clinically in 30 per cent crepitation disappears, and dullness is not so distinct as before. The patient's capacity for work is about 80 per cent.

3 Fibrosa—The pathologico-anatomical condition is the further spread of caseous masses, their liquefaction, and the formation of tuberculous ulcers. Marked dullness may be detected over the affected area with bronchial breathing, and prolonged expiration. Fine moist rales and medium rales as a rule may be heard. There are complications in about 25 per cent. Healing is due to the removal of caseous masses from the bottom of the ulcer, then follows the contraction of the cavity by fibrous tissue. Clinically bronchial breathing and dullness over the affected area are always present, moist rales are absent in about 10 per cent. The capacity for work is relatively about 70 per cent.

4 Ulcerosa—This, pathologico-anatomically, is the spreading of the process with caseous degeneration, and the coalescence of small cavities to form large ones. Over the area of small cavities there is no marked change in the dullness, but a large cavity with thick walls or surrounded by cascating lung tissue, especially when empty, will give, as a rule, a dull note of high pitch with some resonance. On auscultation a low-pitched amphoric breathing is heard, with bubbling rales, crepitations, and also resonant rales. Complications occur in about 40 per cent of the cases. The process of healing is due to the emptying of the cavities and the contraction of their walls by fibrous tissue. Clinically, with the exception of 5 per cent, rales and very distinct amphoric breathing are usually present. The capacity for work is about 35 per cent.

SECONDARY FORMS

If caseous masses are not ejected from the affected area of the upper lobe they may be transferred by aspiration through bronchi and form new foci either in the lower lobe or in the neighbouring part of the lung. In this way they give rise to an exudative caseous process and to pneumonic foci.

A Broncho-pneumonia Metastatica Chronica

1 Fibrosa—Pathologico-anatomically this form is due to the aspiration of caseous masses into one of the bronchi of the lower lobe. There are the same changes in the lungs as in the primary form of fibrous tuberculosis, but between the two affected areas there is a quite normal one. Complications occur in 50 per cent of the cases, and recovery is impossible. The capacity for work is 15 per cent.

2 Ulcerosa—The condition resembles that just described, with the exception of the character of the process, which is the same as in tuberculosis ulcerosa. The incidence of complications and the capacity for work are the same as in the foregoing.

B Pneumonia Tuberculosa Chronica

This form is due to coalescence of many broncho-pneumonic foci, and develops into continuous exudative caseous tuberculosis.

1 Fibrosa—Infiltration or consolidation of nearly the whole lung, with the clinical signs previously described. Recovery is impossible. Complications occur in more than 50 per cent and there is practically no capacity for work.

2 Ulcerosa—Cavities may be found in all parts of the lung. The clinical signs are as previously described. Recovery is impossible. Complications are found in more than 50 per cent, and the capacity for work is practically nil.

In comparison with Turban's classification this one is exceptionally complete. Instead of Turban's third stage it gives a full account of all the progressive changes in the lungs. Turban's third stage does not indicate the condi-

tion of the lungs, but from Gabrilovitch's classification the condition of the pulmonary process may be discerned without further investigation.

This classification shows not only the character of the process, but also the prospects as regards treatment and prognosis—an exceptionally important point. Broncho-pneumonia is always more dangerous than simple pneumonia, the regime in this case must be very severe, and the prognosis extremely grave. Turban's classification gives us no indication as to the nature of the process nor how it spreads. All these considerations are based not on my personal experience only, but also on statistics. If the same area is affected both by broncho-pneumonia and pneumonia, and even if the affected area in the case of pneumonia is the larger, the prognosis is always better for pneumonia than for broncho-pneumonia.

As regards statistics, Turban's "third" stage is silent, and all statistics founded on this classification give not the slightest idea about the nature of tuberculous processes and are of very little value.

The advantage of this classification has been proved statistically. In my work (with Miss Elderton) "Correlation between prognosis based on the condition of the tuberculous patient at entry to a sanatorium, and the issue" (*Annals of Paediatrics*, Vol. II, Parts I and II, April 1927, Cambridge University Press), on page 65 we find: "There is no doubt that the three stages of the Turban-Gerhardt Classification are not sufficient for prognosis, and that the subdivision of Group III by Professor Gabrilovitch's method is an improvement." And further (page 73), as a conclusion: "(2) In estimating issue from stage the Stage III of the Turban-Gerhardt Classification should be subdivided following the divisions used by Professor Gabrilovitch."

COLLOIDAL ANTIMONY IN THE TREATMENT OF TUBERCULOSIS

BY

PLRCEY MONY, M.B., Ch.B.,

TUBERCULOSIS OFFICER AND DEPUTY M.O.H., ROFT AND BOROFGM OF SOUTHAMPTON

In previous articles¹ attention has been drawn to the treatment of tuberculosis by means of intramuscular injections of colloidal antimony (Crookes). A large number of cases have now been treated by this method, and the results obtained are given below. Cases are separated into sputum+ and sputum-, and the sputum+ cases are separated into groups according to the classification adopted in the Ministry of Health Memorandum 37/T.

During the latter half of 1926 196 cases were placed on this treatment, 90 were sputum-, and have nearly all done very well, 3 only having died up to date, but no detailed statement will be made concerning these, as with sputum- cases the diagnosis is open to doubt, and the value of the treatment cannot therefore be demonstrated.

The sputum+ cases numbered 106—11 in Group 1, 23 in Group 2, and 72 in Group 3. No case is included which did not have at least two months' treatment in 1926, and the results are as follows:

	Quiescent	Improved	Not so Well	Died	Left Area	
+1	7	4	0	0	0	July 1st 1927—6 months or more after commencement of treatment.
+2	6	17	0	0	0	
+3	2	56	9	5	0	
+1	7	3	0	1	0	Jan 1st 1928—12 months or more after commencement of treatment.
+2	13	9	0	0	1	
+3	5	34	10	19	4	
+1	7	3	0	1	0	At present—18 months or more after commencement of treatment.
+2	15	5	2	0	1	
+3	7	15	13	32	5	

Four deaths were from other causes, but as the tuberculosis was a contributing factor these are included in the above figures. It will be noted that 67 cases of the original 106 are still under observation or treatment.

Of the cases coming under treatment in the first half of 1927 the following is the result

	Quiescent	Improved	Not so Well	Died	Left Area	
+1	4	12	—	—	—	Jan 1st 1928—6 months or more after commencement of treatment
+2	2	15	1	1	—	
+3	1	25	6	3	—	
+1	9	5	1	1	—	At present—12 months or more after commencement of treatment
+2	6	7	4	1	1	
+3	0	12	5	18	1	

Every case, however severe, is placed on this treatment, and when it is remembered that patients attending municipal clinics come mostly from the poorest section of the community—unsuitably housed, overcrowded, often ill nourished—then I think that the results will compare favourably with those obtained by other methods. With selection of cases for treatment the results would be much better.

Very little change has been made in the method of treatment given in previous articles, except that the colloidal antimony has been increased up to 2 c.c.m. twice weekly, and in cases where the muscle will not tolerate this amount it is given intravenously. So far I have found no contraindications to the use of antimony, and with some 30,000 injections there has been no worse result than a swollen and slightly painful arm.

The present article deals mainly with the results obtained by the use of colloidal antimony, but good results cannot be expected without the usual rest, fresh air, good food and other measures which are generally accepted as essential to the treatment of all cases of pulmonary tuberculosis.

MEDICAL, SURGICAL, OBSTETRICAL

THE PAPILLAE FOLIATAE AND CARCINOPHOBIA

The papillae foliatae are a row of small vertical projections of mucosa on the side of the tongue immediately anterior to the attachment of the palatoglossal folds. Wholly vestigial in human beings, they contain a few taste buds, and represent much larger structures such as are seen in the rabbit. It would seem that but little pathological significance could be ascribed to them, yet during the past few years they have quite frequently come under my attention in two types of circumstances.

In the commoner type they are in no way diseased, but they have caused grave worry to the patient, who both mentally and physically introspective, has discovered at the side of the tongue these warty structures alongside which as a rule a few largish veins are evident. It is characteristic of these cases that the tongue can be protruded almost for its whole extent from the mouth. It should at once be recognized that the sole duty then of the medical practitioner is to make the emphatic statement, "You have not a cancer", with very few exceptions this utterance is rewarded by a look of intense contentment. In some instances, however, they are inflamed—oedematous and swollen—and are causing pain. The infection is from an adjacent molar tooth or tonsillar crypt (the pain sometimes is probably referred along the lingual nerve), treatment is obvious.

C. JENNINGS MARSHALL, M.S. F.R.C.S.,
Assistant Surgeon Charing Cross Hospital

OVERLOOKED ALVEOLAR ABSCESS

In view of the renewed interest in the effect of dental conditions on the general health I think it worth while recording two cases of a condition more obvious than infected pulpless teeth. Such cases are not rare in dental practice, but in view of the prolonged medical treatment that was given ineffectively they may help to direct attention to them at this time.

(1) A girl, aged 13 had noticed pain and swelling on the left side of the lower jaw and had been receiving medical treatment for more than twelve months. Examination revealed the presence

of two diseased roots of the lower left first molar tooth, the crown having broken off. The gums were chronically inflamed from the irritation, but no obvious signs of pus were visible in the mouth. Externally there was an indurated swelling with a discharging sinus. A probe could be passed along the sinus into the body of the mandible. The carious roots were extracted and were found to be surrounded by a mass of granulation tissue and a small amount of pus. A suitable mouth wash was prescribed and at two subsequent visits the socket was examined and syringed once. Two months later the sinus had completely healed up and a year later appeared quite healthy. The scar was still visible.

(2) A girl aged 17 had noticed fifteen months previously a swelling of the lower left jaw region, associated with much pain and tenderness for which various remedies were tried. She was pale and anaemic with almost a chlorotic tinge of the skin. On the left side of the mandible was a raised red area two inches long and $3/4$ in wide. It was indurated and painful on the slightest touch and pus oozed from a sinus. In the mouth a carious lower left first molar tooth was surrounded by highly inflamed gingival tissue and three pea-like swellings containing pus. The breath was fetid and the whole mouth had an offensive odour. On extracting the tooth foul-smelling pus welled up and the roots were very offensive. Pus was expressed and the socket and sinus were thoroughly syringed. The usual treatment at home was prescribed and within two weeks improvement was observable. Two months later the patient's general health and digestion were much better and the swelling and sinus had almost completely healed.

Both these patients had been under treatment for more than a year with no apparent improvement, in the second case, the general health was getting worse, in spite of ultra-violet ray treatment, among other remedies adopted. The most effective treatment for such cases appears to be extraction of the tooth as early as possible, since this nearly always has to be performed eventually, before the condition can be cured. It is, of course, regrettable that teeth especially children's, should ever get to this stage when proper dental treatment of early caries can usually save them.

G. GRAHAM MACPHER, M.B., Ch.B., L.D.S. GLAS

DUPLICATION OF THE TESTICLE

With reference to the interesting account by Mr Edington on June 2nd (p. 937) of a case of duplication or subdivision of the testicle, the following detail of another case encountered a few days after the publication of Mr Edington's article may be worthy of record.

A boy aged 6 was admitted to the North Staffordshire Royal Infirmary with a diagnosis of double inguinal hernia associated with double undescended testicles. On examination the right testicle was felt high up just outside the external abdominal ring. It was smaller than normal in size and could be brought down easily into the scrotum. The ring was slightly enlarged and a definite impulse was obtained when the patient coughed. On the left side no testicle could be palpated and no hernia was demonstrable. A condition of penile hypospadias was present.

Operation.—The right external ring was exposed. A congenital sac was found at the lower end of which was present a small testicle with a well formed epididymis and vas. This was the testicle palpable before operation. About $1\frac{1}{2}$ in higher up the sac a second body exactly similar in size and shape was present. It had a well formed epididymis and vas. No communication between the two swellings was apparent. The two vasa did not communicate as far up as the abdominal ring. The testes measured 1.25 cm in length and 0.5 cm in breadth. The neck of the sac was tied and divided and the distal portion of the sac was left *in situ*. In view of the failure to demonstrate any testicle on the left side it was considered desirable to leave both testicles on the right side.

This case would seem to come into class "B" in Mr Edington's group—namely, pseudo-duplication or transverse ectopia. It is of interest to note its association with hypospadias.

I am indebted to Mr Hartley for permission to record the case.

TRAUMATIC RUPTURE OF TUBERCULOUS ILFO-CAECAL GLANDS

Rupture by violence of tuberculous mesenteric glands is perhaps sufficiently rare to render the following clinical details worthy of record.

A child, aged 5 years was brought to hospital with the story that she had been playing on her sister's back some three hours previously when she had fallen off and her sister had fallen on top of her. The child had at once cried out in pain and shortly afterwards had vomited.

I found the child suffering severely from shock. She had a weak thready pulse of 156 and a temperature of 101.4° F. She complained of pain all over the abdomen and the legs were drawn up. The abdomen moved very slightly on respiration and was almost board-like in its rigidity, and very tender on palpation.

Nothing localized could be made out on palpation, there was no free fluid in the flanks the absence of liver dullness was doubtful. A diagnosis of ruptured viscus was made and immediate operation was undertaken under open ether by Dr. Bark.

The abdomen was opened in the middle line, and some free fluid at once escaped in which were bits of what looked like milk curds. On examining the stomach, however, no perforation was found nor was there any evidence of rupture of the bowel on tracing down the small intestine as far as the ileo-caecal valve. Here, however, to the right iliac fossa, was a big mass which seemed at first to be an intussusception. Careful examination of this, however, revealed it as a mass of tuberculous glands about the size of a tangerine orange situated in the ileo-caecal angle. The glands were soft and in the mass was a ragged cavity from which had come the 'milk curds' we had found on opening the abdomen. The child's condition and numerous adhesions of bowel to the mass made any attempt at resection out of the question, and we had to content ourselves with covering in what raw surfaces we could with peritonium, and closing the abdomen with through and through sutures. Rectal salines were given for the first twenty-four hours, after which convalescence was entirely uneventful.

Six weeks after the operation the child was quite well, she was eating well and sleeping well, and having no trouble with the bowels. She had of course medical treatment during the convalescence and had been in the open air for the last five weeks.

The mass of cascating glands must have been ruptured by the force of the sister's fall on to the child's abdomen, and it was interesting to see what an acute peritoneal crisis was thereby produced.

J SIMS, M.B., Ch.B.

A CASE OF MUSCULO SPIRAL NERVE PARALYSIS

IN view of the comparative rarity of lesions of the musculocutaneous nerve the following case is, I think, worthy of record.

In June, 1927, a papermaker, aged 32, had forebore traction applied to his left arm while it was in the semi-abducted position. As the lower part of the limb had been caught between revolving rollers there was considerable bruising, which extended above the elbow. It was not until this had subsided and he had started to move the joint freely that he noticed that he had little strength with which to flex the forearm and was unable to hold it semi-flexed for any length of time without support. Wasting of the biceps brachii now became apparent, and an area of anaesthesia was found to be present over the outer border of the forearm from the elbow to the base of the thenar eminence. Neither the coraco-brachialis nor the biceps responded to faradism and the reaction of degeneration was present when the nerve was stimulated with the galvanic current.

Some slight improvement has taken place after some months' treatment with the sinusoidal current and massage. There would appear to be a slight reaction to faradism, and the cathodal closing contraction is definitely greater than the anodal on galvanic stimulation. However, the muscle bulk remains the same. The patient shows signs of a return of the appreciation of coarse stimuli in the proximal part of the previous anaesthetic area. He thinks his arm is stronger but has noticed no improvement for the past month.

The main point of interest in this case is that there was no apparent injury either to the lateral cord of the brachial plexus or to the lateral head of the median nerve. Hence the lesion may be accurately localized as being distal to the bifurcation of the lateral cord and proximal to the point of entry into the coraco-brachialis of the musculocutaneous nerve. That some regeneration of nerve has taken place is obvious from the change in electrical reaction. It is therefore assumed that the original lesion was incomplete, or perhaps due to pressure from a haematoma, which later became, in part, absorbed. The question of whether a neurolysis would be of any benefit is now under consideration.

Ottawa, Canada C MERLIN EYNON, M.D., F.R.C.S. Ed.

PIGMENTATION ASSOCIATED WITH LOW BLOOD PRESSURE WITHOUT SUPRARENAL CHANGES

THE following details of a case in which progressive debility, skin pigmentation, and a low blood pressure terminated fatally are of special interest in view of the apparent absence of endocrine abnormality.

A married woman aged 44, was admitted to St. Mary's Hospital for Women and Children, Plaistow on March 3rd 1927, with a history of debility and loss of weight since the previous December, and bouts of nausea, retching and occasional vomiting after food. These attacks had become steadily worse and were accompanied by some pain in the lower lumbar region. The bowels were usually regular. She had noticed brown pigmentation of the face, neck, and wrists for a few months before admission. There had been no previous serious illnesses, and there were six healthy children, the youngest being aged 9.

On admission the patient was well covered. The complexion was sallow, there were small patches of vitiligo on the face and neck, and marked patches on the wrists. There was slight pigmentation of the face, neck, arms, and abdomen. Several achilous stumps were present in the upper jaw. Examination of the abdomen and lungs revealed no abnormality. The heart was normal in size and position, but the heart sounds were weak and the rhythm tick-tack. The central nervous system was normal and investigations of the urine and faeces gave negative results. A fractional test meal showed the presence of complete achylia. A blood count showed red cells 5,128,000 per cmm., total leucocytes 16,000 per cmm., haemoglobin 75 per cent and colour index 0.7. The blood pressure on admission was 100 systolic and 50 diastolic. This rose to 120 systolic before the patient was discharged on April 4th, 1927. With rest and light diet the gastric symptoms had disappeared and the patient felt stronger. She attended the out-patient department for several weeks and improved until the end of May, when she complained of loss of power, and pain in the legs and arms. The blood pressure had fallen to 95 systolic and 45 diastolic.

On readmission on June 2nd the pigmentation was much more marked on the face, arms and abdomen and had now spread to the chest. Patches of vitiligo were present in all these regions. Adrenaline m.t.d.s. was given the blood pressure rose to 110 systolic and 55 diastolic but fell again after a few days to 100/50 where it remained steady. A diagnosis of Addison's disease having been made the chest was examined radiologically for evidence of tuberculosis, but only root thickening on both sides was found. There was no clinical evidence of tubercle. The patient again improved and was discharged on June 21st.

She was again readmitted on August 11th complaining of marked debility and severe pains in the limbs, especially the legs. The pigmentation was more marked. Muscular power in the legs and arms was poor but the reflexes were normal and there was no alteration of sensation. The blood count now was red corpuscles 3,584,000 per cmm., total leucocytes 24,000 per cmm., polymorphonuclears 81 per cent, lymphocytes 15 per cent, eosinophils 4 per cent, the haemoglobin percentage was 55 and the colour index 0.8. The blood pressure was maintained at a steady level of 95-100 systolic and 45-50 diastolic. She was given suprarenal gland gr. j t.d.s., and adrenaline m.v. t.d.s. by the mouth. She seemed to improve and felt better until August 23rd when she complained of nausea and severe shooting pains in the legs and took food badly. The general condition became worse, and on August 31st the blood pressure rose to 115 systolic and later to 130. There was some oedema of the legs and dullness at the base of the right lung. The liver was palpable and tender. No reflexes could be elicited in either leg. Symptoms of heart failure increased, and the patient died at 10.45 p.m. The blood pressure two hours before death was 70 systolic and 40 diastolic.

At the necropsy the heart muscle was thin and showed degenerative changes. No evidence of pulmonary tuberculosis was found but both lungs especially the right were oedematous at the bases. The suprarenal glands showed *post mortem* changes only. The kidneys were slightly enlarged and the left one showed some thinning of the cortex. The other organs, including the brain, showed no abnormality. Sections of the suprarenal glands and of the heart muscle by Dr. H. E. Harding showed that the former organs were normal, while the latter showed myocardial degeneration.

This case was clinically very similar to another recorded by one of us (N.B.) in 1926. In the previous instance, however, there were definite symptoms of hyperthyroidism to account for the sympathetic exhaustion. In the case now reported there were no such symptoms.

Reports of Societies.

MOVABLE KIDNEY

At a meeting of the Section of Urology of the Royal Society of Medicine, held on June 28th, with the President, Mr. FRANK KIDD, in the chair, Professor JURASZ (Poznan) read a paper on movable kidney.

Professor Jurasz said that the well-known mechanical effects of movable kidney were only a part of the clinical picture. The symptomatology of movable kidney was little understood and therefore the disease presented many difficulties in diagnosis. Movable kidney had been wrongly diagnosed as appendicitis, gall-bladder disease, and gastro-ulcer, since the signs and symptoms were often referred to these organs. The clinical picture of movable kidney was not clear-cut, and there was nothing pathognomonic in the disease. Renal symptoms were often slight or absent, and from his wide experience Professor Jurasz only blamed the kidney after careful elimination of diseases of the other

abdominal viscera. He quoted a case of jaundice with symptoms of cholecystitis upon which he had operated and found no evidence of disease of the biliary passages. A movable right kidney was found and fixed, with complete disappearance of the jaundice and symptoms. He believed that the symptoms were due to a visceral reflex spasm of the biliary passages initiated by the movable kidney. The complex symptoms present in patients with a mobile kidney were probably the result of visceral reflexes—viscero-sensory and visceromotor impulses through the sympathetic and para-sympathetic systems. Viscero-sensory reflexes were well seen in diseases of the gall-bladder, etc., and in headache often associated with movable kidney. Visceromotor effects were seen in cases of pylorospasm and spasm of the gastro-intestinal tract as a whole. Vertigo was sometimes present in patients with a movable kidney, and it had been suggested that this was due to stimulation of the vagus nucleus and irradiation from it to the vestibular nucleus.

Professor JURASZ believed that viscerovisceral reflexes led to mechanical disturbances in various organs, and finally might produce pathological results. He mentioned many examples of the effect of visceral reflexes on nerve cells—namely, the thickening of the coeliac plexus in some cases of enterospasm. Also these visceral reflexes produced definite psychical effects. The commonest visceral reflexes were spasms of various portions of the alimentary tract: cardiospasm, spasm of the sphincter of Oddi, spasm of the appendix, etc. This spasm set up a vicious cycle, and the symptoms often persisted after removal of the apparent cause, such as the appendix. Professor JURASZ thought that the movable kidney produced visceral reflexes and on these grounds many of the symptoms of mobile kidney could be explained. The dilatation of the renal pelvis, slight or uniked, could not always be attributed to mechanical obstructions, such as kinking of the ureter, an aberrant renal vessel, or twisting of the axis of the kidney. The speaker had proved by ureteric catheterization, uroteropelography, and by exploration that none of the factors were necessarily present. On the other hand he had demonstrated a diminished motor power of the pelvis of the movable kidney. This was done by timing the return of an indigo carmine solution into the bladder after its injection into the renal pelvis. The time for a normal kidney was four to five minutes. Examination of the urine from a movable kidney showed a definite functional derangement of the organ, since the urea content was diminished, anuria sometimes occurred, and also the specific gravity was low. It had been said that abdominal symptoms could be produced by pressure or kinking of the viscera by the movable kidney but he had never found evidence of this at operation.

Professor JURASZ held very strongly that the involuntary nervous system played the most important part in the symptom-complex of mobile kidney, and consequently diagnosis was often difficult. He had found movable kidneys in children, and he therefore thought that the etiology might be congenital, and also that some cases of pyelitis and nervous instability in children might possibly be due to a movable kidney. Early diagnosis and treatment was most important, because prognosis was bad in cases in which there were secondary changes in the kidney, in other abdominal organs, and in the nervous system. A slightly movable kidney often produced more symptoms than a very mobile organ. Nephropexy was indicated in every case of mobile kidney when diseases of the abdominal organs could be definitely excluded. The presence of renal symptoms was not necessary. He said he fixed the kidney by slinging it to the last rib. His results had been on the whole very satisfactory.

Many interesting pyelograms were shown by Professor JURASZ, demonstrating dilatation of the renal pelvis with no kinking of ureter and no obstruction to the outflow of urine. Pyelograms of movable kidney in children were also shown.

SIR JOHN THOMSON-WALKER said that movable kidney was usually associated with a general visceroptosis and he thought, therefore, that the kidney alone was not responsible for the various symptoms. He said that the drag of the caecum and ascending colon was probably an important

factor in the production of a movable kidney, and therefore if a mobile kidney was fixed the ascending colon and caecum should also be fixed if definitely displaced. He thought that if the mobile kidney produced reflex disturbances these would be more marked in cases in which the kidney was extremely mobile, but this was not the case. He had often demonstrated kinking of the ureter by adhesions passing from the posterior surface of the bowel. Concerning the choice of cases, he did not agree with Professor JURASZ that all cases should be operated upon, but only those cases with definite renal symptoms. Good results were obtained if cases were selected with care. In order to ascertain the type of case to be benefited by nephropexy he put the patient to bed for a fortnight, and, if the symptoms improved, but recurred on getting up, then the case was suitable for fixation. If, however, the symptoms became worse while lying in bed the case was certainly not suitable. Preliminary x-ray examination of the gastro-intestinal tract was also useful in this respect. Sir JOHN THOMSON-WALKER did not think that merely slinging the kidney was all that was necessary. He advised firm fixation to the posterior abdominal wall, thoroughly stripping the capsule from the posterior aspect of the kidney, but not decapsulating the anterior surface, since there was a risk of adhesions forming to the bowel. Fixation of the kidney in the normal position was not necessary as long as the organ was securely fixed and there was no interference with the outflow of urine. He felt that perhaps colopexy should be performed as well as nephropexy.

MR HUGH LERT said that he did not perform nephropexy unless there was definite evidence of renal symptoms or dilatation of the renal pelvis.

MR JOCELYN SWAN agreed with Sir JOHN THOMSON-WALKER that movable kidney was a part of a general visceroptosis and that the adhesions between the kidney, duodenum and gall bladder described by Professor JURASZ were evidence of visceroptosis. He said that slinging of the kidney was good treatment if at the same time the posterior surface of the kidney was thoroughly decapsulated and the lower pole of the kidney was fixed by a suture to the quadratus lumborum. Mr SWAN thought that the dilatation of the renal pelvis may be explained in a few cases by the reflex mechanism the viscerovisceral reflex described by Professor JURASZ, but adhesions at various points around the course of the ureter could often be found on tracing it downwards.

MR F. A. G. JEANS said he only fixed the kidney when there was no evidence of general visceroptosis. Preliminary x-ray examination of the stomach and colon was always made.

MR C. F. NELSON asked how fixation of the mobile kidney removed the source of the visceral reflexes which had been described. Mr FRANK KIDD said that though Professor JURASZ believed that reflex spasms and sensations caused the symptoms of movable kidney yet he advised a mechanical operation to overcome them. He thought it possible that stripping of the kidney to perform nephropexy destroyed nervous tissue which conducted the reflex impulses.

Professor JURASZ in reply said the operation of nephropexy was discredited because a wrong diagnosis was often made. Functional derangement of the pelvis and kidney must occur, since in many cases mechanical obstructions could not be demonstrated. He admitted that certainly not all cases were functional due to a reflex effect, but that some were definitely mechanical. He did not mean that all cases of mobile kidney should come to operation, but only those cases in which after excluding diseases of other organs the symptoms were due to the kidney, though the symptoms were not necessarily renal. Functional derangements gave rise finally to pathological changes as was well seen in rare cases of non-infected gall stones produced by obstruction due to the spasm of the sphincter of Oddi. Fixing the kidney prevented increased stimulation of the nervous tissue and thus the visceral reflexes were abolished. In conclusion, Professor JURASZ said that the whole question of the reflexes of the involuntary nervous system was still difficult and needed investigation, but the functional effects produced by such reflexes must be realized.

Rebuelus.

CALMETTE'S "TUBERCULOSIS"

THE third French edition of Professor CALMETTE's work on tuberculosis¹ has undergone considerable expansion. The most interesting addition deals with the problems of prophylaxis, especially the preventive treatment in man and animals by means of the bacillary preparation introduced by the author and his collaborator, C. Guérin, under the designation "BCG." The bacillary strain employed is of bovine origin, by a series of cultures on bile media it is rendered non-virulent. Living cultures of the "BCG" when injected intravenously into heifers rendered these animals immune against subsequent inoculation by virulent tubercle bacilli. Moreover, heifers immunized by means of "BCG" proved to be protected against infection even while living in close contact with animals infected with virulent organisms. Later experiments showed that subcutaneous vaccination was as protective as the intravenous, or even more so. After satisfying himself by many animal experiments that "BCG" was innocuous a trial was made of this method to protect the newborn infants of tuberculous mothers against infection. Calmette claims a large measure of success in human subjects, he states that up to the end of 1927 the number of newborn infants immunized by means of "BCG" in France had reached fifty thousand. Whether his claims as regards successful protection against contagion in an infected household will be completely substantiated remains to be proved, but even if the achievement should fall below his expectations his efforts must command great admiration.

The plan Calmette recommends is to administer to the infant by mouth during the first ten days after its birth, at forty-eight-hour intervals, three successive doses of bacterial emulsion. Each dose consists of 1 cc of "BCG" in 2 cc of preservative fluid. This dose is given in a teaspoonful of milk warmed to body temperature half an hour before a feed. In many departments and municipalities of France the systematic treatment of infants in this way is being undertaken by official health organizations. The duration of immunity is stated to be from fifteen to eighteen months. If the child is in contact with infected relatives it may be advisable to repeat the "vaccination" at the end of the first and of the third year, but this is said to be not absolutely necessary. The author considers that there is sufficient evidence already to show that a single series of doses will protect children up to the age of 5 years, even though they are exposed during that time to frequent and massive infections from the mother or other members of the family.

There are some further additions to this latest edition of Professor Calmette's book, but it is for the information which it contains upon the use and value of "BCG" that it will be most eagerly read.

DISEASES OF THE STOMACH

DURING recent years there has been a large increase in the number of monographs on the stomach and its disorders, and many of them owe not a little to the published work of Dr. B. B. CROHN and his co-workers. He has now produced his own textbook *Affections of the Stomach*,² and it is a well-documented, profusely illustrated, authoritative volume. Dr. Crohn has sought to approach the subject from the point of view of "pathological physiology," as he calls it, and all that the laboratory workers and radiologists can produce to aid the clinician in his diagnosis and treatment has been well considered and carefully worked into the substance of the book, which has not by any means lost its essentially practical outlook in the process. Moreover, in certain sections Dr. Crohn has obtained the collaboration of experts, as, for example, in the chapter on radiography of the stomach,

written with Dr. S. J. Goldferl, and in an excellent discussion of the gastric neurosis with Dr. A. Kardiner. The classification of non-organic diseases of the stomach presents many difficulties, and Dr. Crohn's discussion of these so-called functional disorders is very clear. He rightly insists that "the most common causes of disturbed digestion (dyspepsia) are bad eating habits, excessive or injudiciously chosen foods, a 'nervous' constitution, or mental excitement during meal times." The chapters on the treatment of gastro-duodenal ulcers and the results of such treatment, medical and surgical, are especially good. An extensive bibliography follows most of the chapters, and Dr. Crohn may claim to have produced a very complete survey of this vast field.

Dr. STANLEY WYARD's *Handbook of Diseases of the Stomach*³ appeared some time ago, and it is noticed here because, like Dr. Crohn's book, it gives a careful clinical presentation of laboratory and radiological evidence. It is essentially a practical work, and the chapters on diet and dietetics and on certain therapeutic measures are especially valuable. On certain aspects of the subject Dr. Wyard states his own views very dogmatically, which may be an advantage for the purpose of teaching, but is not always so acceptable to other workers in the same field. He has little use for bismuth and other drugs in diseases of the stomach, and we gather that in his belief alkalis act mainly by relieving symptoms and "have no curative properties whatever." In discussing the treatment of gastric ulcer (page 283) he states that "medical treatment requires that the patient shall be absent from his work three months at least, present surgical practice necessitates his absence for little more than three weeks." This is surely an overstatement of the facts, for very few, if any, gastro-enterostomy or gastrectomy patients are back at work within a month, and many ulcers are treated medically in out-patient departments with the patients at work all the time and the healing controlled and watched by radiography. Dr. Wyard writes in an interesting manner, and his own views are stimulating. The volume is well produced and gives a good practical exposition of the subject under review.

Dr. F. RAMON's *Diseases of the Stomach and Duodenum*,⁴ in its essentially "Continental" outlook, provides an interesting contrast to the two volumes noticed above. The clinical aspects of symptomatology are especially well handled, and the chapter on aerophagy is very good. An interesting section is on inflammation of the duodenum, "duodenitis and periduodenitis," a topic usually neglected in books on this subject. The chapter on the nervous dyspepsias is instructive, more especially for its view that some underlying gastritis or other real gastric disorder is often present.

AN AMERICAN TEXTBOOK OF MEDICINE

THE time has gone by when it was possible for one man unaided to sit down and compile a successful textbook of medicine, the field to be covered is altogether too wide, and the subjects to be handled call for knowledge too accurate and too complex for the unassisted brain of one individual, however eminent he may be. In the preparation of *A Text-Book of Medicine*,⁵ by American authors, edited by Dr. RUSSELL L. CECIL, no fewer than one hundred and thirty contributors have taken part. This means that every subject has been discussed by a specialist interested in that particular subject. A glance through the list of authors is sufficient to show to what pains the editor has gone to obtain the services of the best talent in America, and this in itself is a guarantee of the sound orthodoxy of the teaching contained in the book. Provided that the

⁵ *A Text-Book of Medicine*. By American Authors. Edited by Russell L. Cecil A.B., M.D., Associate Editor for Diseases of the Nervous System Professor Foster Kennedy M.D., F.R.S.E. Philadelphia and London: W. B. Saunders Company. 1927. (Roy. 8vo pp. xxii + 1590. 29 figures. 40s. net.)

editor maintains harmony and consistency throughout the whole of the contributions the plan of presenting a textbook in which a large number of authorities have collaborated has obvious advantages to the student preparing for his final examination and to the practitioner of more mature years seeking recent and reliable information. Dr Cecil is to be congratulated on the success with which he has brought this magnum opus into being. The information given as to pathology, symptomatology, and treatment is up to date, and the pursuit of pet theories, to which even the greatest may be prone, seems to have been successfully eliminated. The general plan of the work follows closely that of most other textbooks of medicine, but one very commendable feature is the citation of a short list of references at the end of each chapter in which recent work has been mentioned. This should be very helpful to the earnest reader who wishes to extend his knowledge of a subject. The book is well printed and turned out, but is rather bulky and heavy for reading in comfort in an easy chair, but then textbooks are not meant to be read in easy chairs. It certainly deserves a welcome, not only in America, but in all English speaking countries.

MATRIARCHY

MR ROBERT BRIFFAULT'S massive anthropological work in three volumes, entitled *The Mothers*,* is one of exceptional interest from the novelty of its outlook, it exhibits, moreover, a rare degree of erudition and a masterly faculty for handling whole trains of facts which compel our admiration. Apart from his own personal knowledge of the subject, the author displays an extraordinary acquaintance with the literature, and enforces his arguments with details of evidence culled from thousands of sources. The subtitle—"A study of the origins of sentiments and institutions"—indicates that the book deals with the foundations of social development generally, and also definitely propounds a particular thesis—namely, that in the earliest human groups the influence and authority of the female were predominant, and the main object of the author has been to review the development of social institutions in the light of that thesis. A view commonly held has been that in the primitive races the female was systematically oppressed, enslaved, and maltreated by the ferocity of the male. This has undoubtedly been the position in a certain number of degenerate races, as among the native Australians, but speaking generally the popular notion of the treatment of females is a mere travesty of the actual facts, as Mr Briffault pretty conclusively shows. In the earliest social groups the woman was mistress in her own home, was occupied in agreeable and productive work, was the guardian of such accumulated wealth as was available, and possessed full economic control. To the male was allotted the duty of protecting the home and bringing in game, he thus held a position of economic inferiority, and he gained little additional advantage from being the father of the family, for he was regarded merely as the material agent whereby the spirit of the child was introduced into the body of the woman, the children belonging rather to her and her kin than to him. The home thus constituted on matriarchal lines formed the earliest social unit, to call it a family, as we understand the word, would be a misnomer, and the author has made use of the term "motherhood" as being more appropriate. The custom governing the organization of these motherhoods, and permitting their expansion into larger associations without the loss of their feminine constitution, is known as "exogamy," implying that marriages shall not take place within the group, but always with a member of another group. The males under this system either left the parental group and were adopted into the group to which their wives belonged, or they simply visited their wives while continuing to live within their own group. In either case the males married out, while the females remained within their groups and continued to exercise a predominant influence in the home, ensuring its stability and continuity. In these larger associations, as in the smaller

motherhoods, women continued, almost exclusively, to perform those duties which have given rise to material culture. Leather work, basketry, pottery, and building came within their sphere. As the sole producers of manufactured commodities they were the primitive traders, they cultivated the soil and were the keepers of all surplus production, and, further, they were the physicians of the group. It thus appears, according to Mr Briffault's showing, that the primitive social instincts upon which human mental and social development depended were the material instincts and the ties of kinship that derive directly from them.

The matriarchal character of the primitive social order, depending as it did on the economic predominance of women, persisted so long as men possessed no fundable wealth. Definite economic power, it appears, was first placed in the hands of men by the domestication of animals, which were always regarded as appertaining to the province of the hunter, and by the development of pastoral societies. It became a custom for women to be purchased with cattle, to leave their homes, and to live with their husbands, and thus the patriarchal type of society was introduced. Where no domestication of animals took place, as among some North American tribes the matriarchal system still persists, but even where the patriarchal system has become most firmly established, as in civilized societies, traces of an original matriarchal constitution are recognizable in the customs and sentiments of the peoples. Thus the author shows to be the case as regards the Indians, Chinese, Japanese, Semites, Egyptians, Greeks, Teutons, Celts, and Romans.

Mr Briffault's volumes abound in interesting facts relative to the customs, sentiments, and beliefs of primitive peoples, and there is a naïveté about some of these old beliefs which is of considerable charm. We have already alluded to the curious belief that the essential cause of conception was not sexual congress, but the entry of the spirit of the child, and that this might take place through some merely physical agency, such as a shower of rain or puff of wind, thus it happened to a certain Scottish lassie, of whom it is related that as she chanced to be wandering one night on an ancient battlefield, still strewn with the bones of the dead, she "took up her clothes and uncovered herself sum part, when a sudden whirlwind threw some of the ashes in her private member. Whereupon she conceived and bore a son called Gilie Downak Chraivohk."

BIOCHEMISTRY AND CHEMICAL PHYSIOLOGY

THE exhaustion of the first edition of PRYDE'S *Recent Advances in Biochemistry* in the short space of one year from its first appearance has given the author an opportunity of revising and extending his work. In the second edition,[†] which is now upon the market, he has described the more outstanding researches of the year, and where necessary has modified and culled the reviews of various biochemical problems to include new evidence. It is impossible in a brief description to give any account of the subjects with which this book deals, but particular mention should perhaps be made of the chapters dealing with the recent work upon the metabolism of carbohydrates and phosphates, and the structure of carbohydrates—a subject upon which the author can give first-hand information. These are, however, only examples taken from a considerable mass of new material. Indeed as Mr Pryde himself points out, the extreme rapidity of the progress of his subject is well illustrated by the fact that such extensive alterations and additions have already been required. One might add that the necessity for bringing out another edition after so short a time is a testimony to the fact that many readers have appreciated the author's clear and easy style, and his skill in the choice and arrangement of material.

The short textbook of chemical physiology by Professor ERNST SCHMIDT was first published seven years ago. A second and rigorously revised edition[‡] now appears. The

* *The Mothers*. By Robert Briffault. In three volumes. London G. Allen and Unwin Ltd. New York: The Macmillan Company, 1927 (Roy Bro., Vol. I pp. xi + 781, Vol. II pp. xx + 789 19 figures Vol. III pp. xv + 841, 25s net each volume.)

† *Recent Advances in Biochemistry*. By John Pryde B.Sc. St. And. M.Sc. Wales. Second edition. London J. and A. Churchill 1928 (5s.) x + 379 38 figures. 12s 6d net.)
‡ *Kurzes Lehrbuch der Chemischen Physiologie*. Von Dr. Ernst Schmidt. Zweite neubearbeitete Auflage. Berlin S. Karger 1927 (6s.) x + 383 16 figs.)

book follows conventional lines. The early chapters are devoted to the chemistry of the major constituents of protoplasm, and are followed by others in which the special chemistry of individual organs and the functional aspects of biochemistry in digestion, respiration, internal secretion, and total metabolism are considered. From the scope of the book it would appear that it is intended for medical students or other students of science first entering upon the study of biochemistry. By such it will be much appreciated, provided they have that measure of chemical experience which will permit them to comprehend the great wealth of detail which the author has managed to cram within the covers of this small volume. The text is liberally annotated with references to the original literature and the author claims to have surveyed the literature up to the middle of 1926. The book is certainly up to date, but in saying this we do not mean to suggest that the author is forever seeking new gods for his selection from recent work is restrained and judicious.

A GUIDE TO TRAINING

Mrs H. M. ABRAHAM and Dr A. ABRAHAM are particularly well qualified for the task of writing a book on *Training for Athletes*,* for they both possess the experience of distinguished track athletes, and one of them has the medical and physiological knowledge which is necessary for any authoritative statements as to methods of training. Not content with their own knowledge they have enhanced the value of their book by enlisting the help of Lord BURGHLEY, Messrs D. G. A. LEWIS, I. R. GARY, B. HOWARD BAKER, and M. C. NOKES in the articles on the special subjects in which those gentlemen have distinguished themselves. Naturally this book is more concerned with running and jumping than with rowing which leaves far less to the choice of the individual than does the racing track. Although this is only a small book its 180 pages seem to contain all that it is possible to teach in a book about training and competing, including the necessary physiological facts expressed in language comprehensible to the non-medical reader. Some conception of the effort involved in running one hundred yards at full speed may be got from the statement, made on the authority of Professor A. V. HILL, that a creak sprinter accumulates in his muscles in those ten seconds 40 grams of lactic acid, an amount corresponding to that accumulated during twenty-seven minutes at rest. As all this acid has to be removed by oxygen inspired, the necessity of good lung and heart capacity is evident to the least scientific reader.

If the absurd and oppressive regimen of beef *ad libitum* and beer in moderation still lingers in the training of cricketers at our older universities the authors of this book are more enlightened, for they sanction all wholesome digestible food in a diet including a due proportion of protein, fat, and carbohydrates, and as to alcohol they use no uncertain language. "We are of opinion," they write, "that alcohol is quite unnecessary to an athlete, and we strongly deprecate the advice often given to regard it as a useful 'tonic' in training." The necessity of well-fitting shoes is properly insisted upon, but we are disappointed to find no statement as to their shape. Such running shoes as we have seen have all tended to be pointed and to preclude the free and proper use of the great toe. We are shown what a great cumulative difference a very small disadvantage may cause in the course of a race of only one hundred yards in which six inches at the tape makes all the difference between victory and defeat. It seems possible that a properly acting great toe might give just such a small but final advantage over the abducted useless digit in a pointed shoe.

The authors take a sane and balanced view of the question of athletics for women, and while allowing that some girls who anatomically approximate to the male type may excel, they hold that, except for swimming, women's development is less adapted to athletic excellence than men's, and that perhaps severe physical exertion is to be deprecated when practised by potential mothers.

* *Training for Athletes*. By H. M. ABRAHAM and Dr A. ABRAHAM in collaboration with Lord BURGHLEY, D. G. A. LEWIS, F. R. GARY, B. HOWARD BAKER, and M. C. NOKES. London: C. Bell and Sons Ltd. 1928. (Cr. 8vo pp. xviii + 183. 12 plates. 6s. net.)

NOTES ON BOOKS

L'Année Médicale Pratique,¹⁰ under the skillful editorship of Dr CAMILLE LIAN, continues to provide a vast amount of information which is in many ways of interest and value to English readers. The main part of the book consists of articles on a wide range of subjects, written by experts and arranged in alphabetical order, and it concludes with a section on professional matters, a list of new pharmaceutical preparations, and a subject index to the previous six volumes. It is a work that should be better known to the profession in this country.

The seventh edition of the late Dr GWYN DAVIS'S *Applied Anatomy*¹¹ has appeared, edited, as before, by Dr G. P. MULLER. Many of the sections have been rewritten, and accounts of new procedures, such as cervical sympathectomy and the Billroth and Polya operations, have been added. The excellent series of illustrations has been further improved by corrections of some errors in previous issues and by the addition of new figures. The considerable amount of revision which has been performed has made this extremely useful book even more valuable than its predecessors.

Professor E. SELIGMANN'S work on the control of infectious diseases¹² is a collection, as its subtitle states, of lectures delivered at the Charlottenburg Academy of Social Hygiene. The work is divided into two unequal parts. The first or general part includes chapters on the principles of epidemiology including experimental epidemiology in which the work of Topley and Webster receives recognition, on the transmission of disease and susceptibility to disease, and on the legal principles of control of infectious disease, including international sanitary conventions and disinfection. In the second part, which forms the bulk of the work, the various infectious diseases are considered under the headings of infections (1) of the respiratory tract, (2) alimentary canal, (3) blood, lungs, and nerves, and (4) skin and mucous membranes. The appendix contains a variety of miscellaneous information arranged in ten sections, including a list of diseases notifiable in different countries, a summary of the mortality from tuberculosis in the two hemispheres, and various German sanitary enactments, of which the most interesting is the law passed in February, 1927, for the control of venereal disease.

No doubt some of the movements, exercises, and procedures described in *The Technique, Effects, and Uses of Swedish Medical Gymnastics and Massage*,¹³ by Dr J. ARVEDSON, and translated by Dr MINA L. DOBBIE, are of proved value in various conditions, but a perusal of this book leaves us somewhat sceptical of the practical effect of some of the more complicated. For instance we find difficulty in persuading ourselves of the therapeutic efficacy of sitting nose root shaking. In this process "the gymnast grasps the patient's occiput with one hand (in itself a difficult task for a woman, and the illustrations show all female gymnasts), while the other grasps the root of the nose and performs a shaking as forcibly as necessary to affect the chronic catarrh on the mucous membrane of the nose. Sometimes combined with wing stoop stride sitting back raising. (See page 205.) We cannot help thinking that "as forcibly as necessary" must be very forcibly indeed if it is to relieve chronic catarrh, and we should personally prefer the catarrh to the cure. The above quotation is an example of the cumbersome compound titles or words of command given to many of these proceedings but for all that, one of the shortest—namely "talk standing"—is the most incomprehensible. We learn that talk standing arises by rotation outwards of the arms and hands, and that

it is used to produce a slight expansion of the chest. No doubt talk, if loud enough, may produce expansion of the talker's chest, but except among deaf mutes it is seldom performed by movement of the arms and hands. Is there a mistranslation here or are we betraying ignorance of Swedish massage jargon? Apart from all this, however, there is much in the book of value to masseuses. In particular the movements and exercises for the remedial treatment of scoliosis seem to us practical and beneficial. The illustrations are many, but their value is much reduced by the circumstance that all the patients are represented as fully clothed. Judging from these figures, Sweden appears to be still in the long haired, black stocking stage, which with us is now only a memory.

¹⁰ *L'Année Médicale Pratique*. Publié sous la direction de Dr Camille LIAN. Septième édition. Paris: R. Lépine. 1928. (Fcap. 8vo pp. 651, 7 figures. 24 fr.)

¹¹ *Applied Anatomy*. By Gwyn DAVIS, M.D. Seventh edition revised by George P. MULLER, M.D. London: J. B. Lippincott Company. 1927. (Sup. roy. 8vo pp. xii + 638. 656 figures. 42s. net.)

¹² *Seuchenbekämpfung*. Vorlesungen an der sozialhygienischen Akademie Charlottenburg. Von Professor Dr E. Seligmann. Berlin: S. Karger. 1927. (Sup. roy. 8vo, pp. 282. 18 figures. M 16.60.)

¹³ *The Technique, Effects and Uses of Swedish Medical Gymnastics and Massage*. By Dr J. Arvedson. Translated by Mina L. Dobbie. M.D. B. Ch. London: J. and A. Churchill. 1927. (6½ x 8½, pp. x + 269. 131 figures. 12s. 6d. net.)

*Allen's Commercial Organic Analysis*¹¹ is a handbook of instruction in methods of analytical examination dealing more especially with materials which are wholly or principally of organic composition. The book is representative of a great variety of subjects, including, besides articles of food and substances used in medicine, a wide range of materials used in the arts. Our comments on four volumes of the book have already appeared. Volume v, which is now before us, deals with inks, leather, and the artificial colouring of foods; it includes also benzene and aniline, together with an assortment of substances more or less related to them. Each of the subjects is treated as a distinct section and is the work of a contributor chosen for his experience in the particular subject. Of the contributors four are citizens of the United States, while five belong to this country. In this volume a number of therapeutic substances are described, including several of the pyrazolone group, to which antipyrine belongs. The work appears to have been treated on the best plan possible for the purpose in view, and although it incorporates a good deal of matter taken from original memoirs in unaltered or slightly altered form, there is much besides, which represents exhaustive labour by the writers. It is a book that practising analysts cannot well do without. Volume vi is of the same character. It is concerned wholly with dyes and colouring matters. It is divided into four sections, dealing separately with their properties, constitution, identification, and methods of colorimetry. The treatment of the subject is comprehensive, and the information always appears easy to find.

¹¹ *Allen's Commercial Organic Analysis*, Vols. v and vi. Fifth edition revised and in part rewritten. Editors: Samuel S. Sadtler, S.B., Elbert C. Lathrop, Ph.D., C. Ainsworth Mitchell, F.I.C. London: J and A Churchill, 1927 and 1928. (Med. 8 o vol v pp xii + 700 6 figures; vol vi pp ix + 658 304 each volume.)

PREPARATIONS AND APPLIANCES

ARTERY FORCEPS AND LIGATURE CARRIER FOR DEEPLY PLACED VESSELS

Mr E. MILNE EATON (London W.) writes: The forceps of which the jaws are illustrated in the figure have been designed primarily for the application of ligatures to vessels in the tonsil bed. The difficulties to be overcome are to get the loop of the ligature over the tip of the forceps without stripping off the grasped tissue and in tightening the knot to apply tension to the ligature in a direction strictly transverse to the axis of the forceps.

The terminal part of the instrument is deeply tapered and its sides are recessed to give accommodation for the lateral parts of the wedge of tissue raised from the general surface level thus avoiding its detachment in tightening the loop. The carrier consists of a short cross piece with a hook at each side and a straight stem slightly longer than the forceps with, for handle, a small roughened sphere. By its means the ligature is pushed forward into position and the direction of pull is altered to become parallel to the tissue surface.

and in the case of soft tissue such as that of the pharyngeal wall it is unnecessary to remove the forceps until the procedure is completed.

The length of the instrument is $7\frac{1}{2}$ in., but a 5 in. size is available for general surgical use. It will be found of value when owing to lack of assistance or to the site of application a ligature has to be applied without elevation of the tip of the forceps. The use of the carrier is of course unnecessary with the smaller forceps or with the larger one when applied in moderately accessible positions. The instruments have been made for me by Messrs. Mayer and Phelps, London, W.

TRIMINTRIN CAFEINÉE.

Trimintrin caféinée Dubois are pills containing 0.03 gram of liquor trimintrini (1 per cent solution) and 0.02 gram caffeine. The pills are sugar-coated with a soft centre, and are intended to be masticated. This permits the immediate absorption of the trimintrin through the mucosa of the mouth. The preparation appears to be a convenient form of medication for use by cases of angina pectoris. The distributing agents for the British Empire are the Anglo-French Drug Co., Ltd. (238a, Gray's Inn Road, W.C1).

LONDON ASSOCIATION FOR MENTAL WELFARE

ADDRESS BY DR MAPOTHER ON "THE PSYCHIATRIC CLINIC"

THE annual meeting of the London Association for Mental Welfare, presided over by the Hon. Lady LAWRENCE, J.P., L.C.C., was held at the Royal United Services Institution on June 27th.

In giving an account of the work of the year, Miss K. T. WALLAS, L.C.C., chairman of the council, spoke of the several masters which the association had to serve. A part of its work was statutory and a part voluntary. To the first category belonged the work it did for the Mental Hospitals Department of the London County Council by supervising in their own homes all cases subject to be dealt with under the Mental Deficiency Act, and by the conduct of occupation centres for these children, also work for the Ministry of Labour in the placing and after care of mentally defective boys and girls; and, further, the inquiries it made on behalf of the London Education Authority regarding children leaving special schools at the age of 16. The work for voluntary cases for which the association received a grant from the Board of Control was again many-sided including, in the first place, the aiding of those who needed care and protection to secure this through the Mental Deficiency Act as afforded by homes and institutions and the supervision of those who were to some extent able to become partially self-supporting but who without this friendly guidance, would be unable to do so. A very important feature of the voluntary side of the work was the watch and guard maintained over those who though undoubtedly weak in character and subnormal in intellect did not come within the scope of the Act and could not therefore be helped through legislative provision. During the past year roughly 4,000 cases had been assisted on the statutory side of the association's task, and 4,000 others on the voluntary side. The number of youths and girls placed in employment had been 675. Miss Wallas spoke in moving terms of many encouraging features in the work.

Lord STRATHCONA, who has lately become treasurer of the association, presented the accounts which showed an income of £6,300 97 per cent of which was in the form of grants from the public bodies just named.

An address on the work of a psychiatric clinic was then given by Dr E. MAPOTHER, medical superintendent of Maudsley Hospital. Dr Mapother defined such a clinic as an institution which attempted to carry out on a voluntary basis the treatment of curable mental disorder. The distinction between mental disorder and mental defect always rather artificial was becoming more so. Formerly there were two more or less distinct groups of cases—namely those originating before or shortly after birth and those occurring not before adolescence, the two being separated by the years of childhood. But now this fairly long gap in between was being filled up by cases of post-encephalitis lethargica and its sequels. This new state of affairs had been recognized by the law in making the provisions of the Mental Deficiency Act applicable to cases practically of adult life. Conditions like delinquency had always been common territory to mental defect and disorder, and, moreover, there were a large number of slightly subnormal people who developed acute psychoses on top of the subnormality and who came under treatment for a short time, but otherwise were able to live quite useful lives. Unless there was to be an extravagant duplication of arrangements a good many such arrangements should be common for the borderline cases of mental defect and disorder alike. In connexion with the arrangements for the treatment of mental disorder there were four main considerations: the ability of the patient to pay for his treatment, the severity of his malady (practically his certifiability or otherwise), his willingness or unwillingness to receive treatment or indifference thereto, and the question of prognosis. At present the situation was dominated by the first two of these considerations. England was about thirty years behind Germany and Holland and the most progressive States of America in respect to the arrangements for early mental cases though in respect to established cases of mental disorder there was practically no country in the world where the arrangements were as good. The present position in most places outside London—London was far ahead of the rest of the country—was that treatment of mental

disorder at public expense was only to be obtained when a case was bad enough to be suicidal, or a burden, or a nuisance. In his view the clinic might take in a certain number of cases ordinarily certifiable, such as those with suicidal tendencies, provided they were willing to accept treatment. If the psychiatric clinic was to be a training ground for such workers as those embraced by the Association for Mental Welfare—and it was the educational function of the clinic, alike for members of the medical profession and for social workers, which was of the greatest importance—it was necessary that it should cover the widest possible range of cases, so long as the principle of voluntary treatment was not infringed. As to whether the public wanted clinics, he thought the experience of Maudsley, where they had disappointed the expectations of those who had said that within two years of its foundation it would become an ordinary mental hospital for certifiable cases, supplied the answer. As for the question of cost, the maintenance of a patient in a psychiatric clinic was about the same as in a general hospital, and a good deal less than in

a mental hospital. The addition of private wards assisted considerably in reducing the overhead expenses. He thought that psychiatric clinics should be run by local authorities, without such assistance they were crippled for lack of funds, and were not able to provide the wards, personnel, and facilities. The difficulty of public apathy on all matters connected with the treatment of mental cases had to be overcome.

Dr LITITIA FAIRFIELD also added some remarks on the care of the delinquent defective, based on her experience of the female delinquent (using delinquency in the narrow sense of criminality) notified from police courts to the Mental Hospitals Department of the London County Council during the last three years. The total number of these was only 49—a very small number in comparison with the male delinquents. The crimes with which these girls and women were charged were in nearly all cases of a trivial character, obviously arising out of failure to adjust themselves to the responsibilities of life.

UNIVERSITY COLLEGE, NOTTINGHAM

THE NEW BUILDINGS

WHEN the British Medical Association held its Annual Meeting in Nottingham in 1926 members were given an opportunity of visiting the New University College Buildings, then in progress. The main buildings are now complete, and the University Park is laid out to the fullest advantage both as regards beauty and recreation. The whole city is looking forward with pleasurable anticipation to the opening of the new buildings on Tuesday next, July 10th, by His Majesty the King. An appeal has gone forward, and much has already been done towards raising the £250,000 required in endowments if the New University is to obtain its charter.

The present University College has developed step by step from the first adult school founded in this country 130 years ago by the Quakers of Nottingham. In 1877 the present buildings in Shakespeare Street were commenced, the town council of the day being pledged to give its support. The Treasury inspectors stated in the 1890 report that "the Nottingham University College exhibits the nearest approach of all colleges which we have visited to a people's university."

In the year 1913 the College Council had decided that the scope of the work of University College was extending, and that the time was approaching when every effort must be made to raise it to the status of a university. Unfortunately, the outbreak of war and the difficult post-war conditions made it impossible for them further to develop their projected schemes. Meanwhile, the ever-growing needs of the college were being met as best they might. New departments were housed in any available premises in the vicinity of the college, and the chemical, physical, and biological laboratories, though extended, had completely outgrown the old buildings.

It was at this point that Sir Jesse Boot, Nottingham's great benefactor, came forward with gifts unparalleled in their generosity. His realization of the difficulties that beset the chemical department led to his first gift of £20,000 to endow a chair of chemistry. As he came into still closer touch with the college he felt the urgent necessity of moving it from the centre of the city to some place

where there could be adequate buildings, possibility of extension, and opportunity for recreation. He then gave £30,000 to form the nucleus of a building fund, and, to make his ideal possible as he visualized it, he presented a site of almost 50 acres to be laid out as a University Park.

From that time onwards Sir Jesse Boot has not ceased giving, and the buildings, erected at a cost of £285,000, have been his princely gift to his native city. His first intention was to erect the main buildings, leaving the Great Hall and the Women's Hostel to be built later. But

so appreciate was he of his architect and his manager, and of the skill of the workmen engaged on the building, that he promised to guarantee the cost of the building of the Great Hall if it were not possible to defray this by public subscription. His enthusiasm grew as the work progressed, and he eventually decided to bear the expense of the entire building himself.

Lady Boot, equally enthusiastic, associated herself with the work, and offered to build the Women's Hostel, for which plans had already been got out. This undertaking was estimated to cost £45,000 and it was indeed a great burden which she took from the shoulders of the women of Nottingham when she gave so generous a promise.

One of our chief reasons for coming to this decision, says Sir Jesse Boot, is to avoid confusing the public mind by simultaneous appeals both for the actual building of the university and for its endowment. We thought it would simplify matters very much if the appeal to the public could be solely for the endowment fund, and

At the moment of the opening by His Majesty the King, when the stones of the coming university are still unweathered by time, it is difficult to appreciate the full significance of this educational development. Thousands of students yet unborn will pass along these corridors and learn in the lecture rooms and wrest the secrets from Nature in the laboratories. Their work will link still more closely industry with science, add to the honour of the city, and help to increase the well being of our nation.

The whole scheme has been fortunate in its architect, Mr P. Morley Horder. The beauty of the new buildings, situated almost on the crest of the hill, can be appreciated from different points for many miles around. The campanile adds grace to a building of simple dignity. The

UNIVERSITY COLLEGE, NOTTINGHAM.

entrance hall is below this tower, the Great Hall and the library to west and east giving balance to the stately proportions of the façade. From the south front a wonderful prospect can be seen of the park, the open air swimming bath, the lake—once a pond, now a beautiful pleasure lake of 14 acres—the pavilion by the lake side, the new University boulevard, its playing fields and tennis courts, and the distant Trent flowing “sing and silver” by its wooded hills.

On the east of the entrance hall is the council chamber, oak-panelled, approached by marble corridors. At the extreme end of the east corridor is the library, occupying two floors in height and of noble proportions. The Great Hall is at the extreme end of the west corridor. It is built entirely of Portland stone and, but for the ceiling, is austere in its simplicity. A colonnade runs round the gallery, the front of which is carried out in oak. The ceiling is flat, with plaster enrichments in colour. Below the Great Hall is a lesser hall, while under the library there is the refectory, the corridor rooms on the lower floor being used as common rooms, staff rooms, and dressing rooms.

Grouped round the three courts on the ground floor are museum laboratories, and workshops. The first floor gives accommodation for lecture theatres and larger classrooms, while on the second floor are the examination rooms and private research laboratories and studies. Mention should also be made of the extensive laboratories at the disposal of the departments of physics and inorganic chemistry, each of these having an area of more than 2,500 sq ft. The crying need for these new larger buildings will be readily understood when it is realized that in 1926-27 there were in all 2,275 students at the college. Last year 68 took degrees, and 258 received diplomas.

It is impossible to mention in so short an article many of those who have been inspired by the generosity of Sir Jesse Boot to contribute to the coming University. But the citizens of Nottingham remember with gratitude the never-failing sympathy and encouragement which they have received for many years from His Grace the Duke of Portland, President of Court of Governors, nor will the name of Alderman Huntsman now Mayor of Nottingham, be forgotten. He has devoted years energy, and all the force of his own strong idealism to this project. As chairman of the College Council he has guided the destinies of the University College with a sure hand and with high hopes for its future.

Our illustration from a sketch of the South Front is reproduced by permission of Messrs Jenkins and James publishers Nottingham.

RADIOTHERAPY OF UTERINE CANCER

METHODS, RECORDS, AND RESULTS

IN accordance with a report by the Cancer Commission to the Health Committee of the League of Nations in May last a subcommission of experts was appointed to study the radiotherapy of cancer, with special reference to cancer of the uterus. Emphasis was laid in this report on the importance of collecting data from different sources regarding the methods of radiological treatment and their modern results. In addition, it was suggested by the president of the Cancer Commission, Sir George Buchanan (senior medical officer of the British Ministry of Health) that it might be well for the subcommission to take cognizance of the following points: (1) Available supplies of radium. (2) The centralization of radium in each country for the supply of the smaller clinics and individual practitioners, in the event of this being considered desirable. (3) The form of record which should be kept with the view of comparing the results obtained in different countries after some five years' observation after cessation of treatment.

The subcommission includes the following experts in radiology and gynaecology:

Professor CL. REGAUD, Director of the Radium Institute of the Curie Foundation, Paris (President).

Mr. CONYERS BEEBELEY, Director of the Gynaecological Service, Middlesex Hospital Cancer Charity.

Professor DODERLEIN, Director of the Gynaecological Clinic of the University, Munich.
Professor W. LAHR, Director of the Laboratory Research Work, the Stoto Gynaecological Clinic, Chemnitz.
Professor VAN ROOY, Director of the Gynaecological Clinic of the University, Amsterdam.
M. R. LEROUX, Chief of the Therapeutic Works at the Curie Foundation, Paris.
Professor VOLTZ, Gynaecological Clinic of the University, Munich.
Professor G. FORSSELL and Dr. HEYMAN, Radiumhemmet, Stockholm.
Professor PESTALOZZA, Director of the Gynaecological Clinic, Rome.
Dr. JANET E. LANE-CLAYTON (Investigator), attached to the Departmental Cancer Committee of the Ministry of Health, London.

The first preliminary meetings of the subcommission were held on June 18th and 19th, and were attended by the president of the Cancer Commission. Detailed consideration was first given to the nature of the information to be collected and the sources to which application should be made. It was considered necessary to obtain individual details of a numerically large series of cases of cancer of the uterus, classified according to their treatment: (a) by radium, (b) by x rays, or (c) by both, taking account only of those cases in which the treatment was completed more than three years ago, and in which the later histories were traceable, it will also be necessary to have statistical data of all observed cases in each of the clinics taking part in the inquiry. The details to be given were settled, but the subcommission left the preparation of model forms, cards, etc., to the Health Secretariat of the League, which, for this purpose, will have the advice of Dr. Lacassagne (Paris), Professor VOLTZ (Munich), Dr. Heyman (Stockholm), in addition to that of Dr. Janet Lane-Clayton, who has been appointed the technical inquiry officer of the commission for this purpose. The same group of experts will assist in the collection and codification of the replies received.

The clinics and institutions to be applied to are to be limited, in the first instance, to those which possess a sufficiently large experience, and their assistance may be invited either directly or through national health administrations or other appropriate national organizations.

As some cancer or gynaecological clinics have already expressed their willingness to co-operate in an inquiry whose practical value they recognize, it is hoped that these data may be collected without delay. It is intended that the results, when analysed, should be submitted in the form of a report to the Health Committee of the League, and published in due course. While the clinics or institutions chosen will be specially requested to follow the system of record proposed to them for purposes of international comparison, they will also be invited to summarize their own observations and views regarding the efficiency of radiological treatment in any manner which they consider may be useful to the Commission. The inquiry as such is to be limited to uterine cancer (cervix and body), but necessary information regarding cancer of other gynaecological sites may be supplied for separate study.

On the broader questions relating to the treatment of uterine cancer by radiology the president, Professor Regaud, submitted a series of considerations which, after a general discussion, were adopted by the subcommission as representing the most important directions to which its future discussions should be directed, and on which definite recommendations should be made in due course to the Health Committee with a view to publication. Among these considerations were:

1. Propaganda among doctors and the general public in order to ensure the early discovery and early and correct treatment of cancer of the uterus.
2. Increase in the number of consultation centres.
3. Organization of centres for microscopic analysis in order to ensure early diagnoses.
4. Recommendations for the organization of the correct treatment of the disease.
5. Recommendations for the radiotherapeutical equipment of clinics.
6. Disadvantages of out-patient treatment.
7. Recommendations for the compilation of reliable statistics.
8. Recommendations for special scientific research.

The Commission also noted, as subjects for inquiry, the available supplies of radium and the need for an authoritative opinion as to the advantages and drawbacks of distributing radium or radium emanations to hospitals and individual practitioners.

AMERICAN ANALOGIES

THE resemblance between the American Medical Association and the British Medical Association is as great as the similarity of names implies: many analogies can be found in their machinery and procedure. As is only natural in a country whose population has quadrupled itself in three generations, the American body, though seventeen years younger than its British counterpart, has a membership twice or three as large, and with ampler resources it undertakes some public duties at present beyond the means of the organized profession in these islands. Apart from differences of size and scope the two Associations have a great deal in common and work on corresponding lines. With each the turning point of its year is a congress in some large centre for scientific and medico-political business, and just as our own Association is about to hold its ninety-sixth Annual Meeting at Cardiff, so the A.M.A. has lately held its seventy-ninth annual session at Minneapolis. Each also invites on these occasions distinguished colleagues from abroad. Among those taking part in the scientific proceedings at Minneapolis three weeks ago was Sir Jentah Chentle and his address on cancer is printed in the opening pages of our present issue. At Edinburgh last summer we welcomed as a delegate of the American Medical Association its president elect, Dr W. S. Thayer, Eminent Professor of Medicine in Johns Hopkins University, whose discourse at Guy's Hospital during the Richard Bright centenary celebrations appeared in these columns about the same time.¹ Professor Thayer has now succeeded to the presidential chair and his inaugural address at Minneapolis is before us.² It is a note-worthy address, eloquent, thoughtful, suggestive, and will well repay perusal in full. It surveys a great deal of ground—the ideals and characteristics of the medical profession, the specific amenities which the Association offers to its members, medical education and the organization of clinical instruction, the corresponding training of nurses, the relation of the practitioner to communal health activities and lay public health organizations, the effects of the growth of specialism and the elaboration of diagnostic methods on professional relationships. Many wise words are said on these subjects, and they serve to bring out the essential similarity of views, aims and methods of the American and the British Medical Associations, together with some not unimportant differences in the conditions under which they work in the Republic and in the Empire.

The American Medical Association has in the United States to perform the functions not only of the British Medical Association but also as far as possible, of our General Medical Council. It has to be the great guardian of the standards of medical education and of medical conduct in the interests of the public. Its task in this regard is not easy, and without its influence both these standards would be lamentably lowered. Though in Great Britain these matters are the prime duty of the General Medical Council, it must not be overlooked that the British Medical Association is in no small degree also con-

cerned with them. It is a powerful means of formulating and encouraging correct professional behaviour, and is constantly vigilant, so far as the imperfect constitution of the General Medical Council will allow, in securing that, in the matter of medical education, the views of those who are trained receive consideration as well as the views of those who conduct the training. Professor Thayer refers to the admirable report of Mr. Abraham Flexner on the medical schools of America, and to Sir Andrew Macphail's address on "American Methods in Medical Education," which was printed as the principal article in our last Educational Number,³ and he well reminds us of the influence which general professional ideals must have upon education as well as upon conduct, and of the reciprocal influence of a wide basic education upon conduct and ideals. Even within the bounds of strictly medical training the specialist who has not had a good basic medical training is a danger to society. 'Too early specialization is one of the great faults of American education.' With us it is perhaps not so much too early specialist training as the absence of some degree of wider medical experience which is the danger in the development of specialism.

The spread of specialization is causing great changes in medical practice. Both the time and the expense entailed by a complete physical investigation of a patient have much increased, and there is a marked tendency towards group practice and co-operative clinics. Professor Thayer warns us that this is not always wise, in so far as it diminishes the opportunity for the exercise of the most vital and important element in the practice of medicine—the human influence, the close personal association between doctor and patient. Experience and wisdom are worth many instruments. Our main functions, our immediate duties, are 'to care individually for our patients, to treat them when ill, and to give them such advice that they may preserve their good health, to prevent the spread of disease from our patients to others within the household or outside, to co-operate in every respect with local boards of health in the early reporting of registrable disease and through scrupulous attention to all prophylactic measures.' Professor Thayer adds some wise words, useful here as well as in the United States, with regard to the wider duties of the medical profession in relation to public health. He reminds us that we share these duties with the public. It is on the medical profession that the burden of special competence, and therefore of special responsibility, lies. Individually and collectively we are especially qualified to advise the public in these matters. We must seek to direct the public toward sane and efficient action. Yet 'in the broader matters of public health the public has the same right, after seeking what advice it will, to take just what action it chooses: neither as individuals nor as an association have we the right to demand that the public accept our views.' Members of both Associations, impatient to realize their ideals and zealous in professional and public interests are liable to forget this truth. Both these great medical Associations are in a peculiarly delicate position. 'Do what we will we shall be accused of selfishness, of attempting to protect our own personal interests, of using our power as an organization to oppress others. We must be careful to see that such reproaches are wholly unjustified. The rarest and most valuable of human qualities is the ability to square one's ideals with the realities of existence. We must as a profession and as an association make this effort.'

¹ *British Medical Journal* July 16th 1927 p. 87.

² *Journ. Amer. Med. Assoc.* June 16th 1928 p. 1917.

³ *British Medical Journal* September 3rd 1927 p. 373.

Happily, the history, the work, the accomplishments of both the Associations show that such accusations are, in fact, without foundation, and that, in maintaining the honour and interests of the profession, there has been equal care and success in the advancement of medical science and the promotion of the public good.

Professor Thayer's final appeal to certain members of the profession is worth quoting in the hope that it may not be without its effect in relation to the British Medical Association. In this life," he says, "there are always those, often superior men and women, who are so occupied with their special interests and pursuits that they lose touch with the larger activities of life. Such are very likely, subconsciously, to manifest a certain impatience with public movements and discussions. From the privacy of their peaceful abode they are prone to regard with suspicion and distrust those who enter into public life. There are such men in our own profession who, rarely departing from the quiet round of their existence, look on those who direct the functions of this body with something of suspicion. I wish that some of these men might have the opportunity that has been given to me to see the working of the central organization of this Association. They could only feel, as I do, a sense of the deepest admiration for the character and devotion and idealism of those men who represent us and they could not fail to marvel at the magnitude and the beneficence of the work they have accomplished and are accomplishing."

POOR LAW AND LOCAL GOVERNMENT REFORM

THE Minister of Health has just issued to local authorities a Parliamentary Paper¹ expounding the third but not final, version of the Government's proposals for Poor Law and other local government reforms. The first version was described in our issue of December 12th 1925 (p. 1136). In this connexion a special committee was set up by the Council of the British Medical Association early in 1926 to watch the matter, a memorandum on the subject was prepared and this memorandum and the comments of the Committee on the Minister's tentative proposals were endorsed by the Council a little later and by the Representative Body, after a full discussion (reported in the *Supplement* of July 31st 1926) at Nottingham. A revised scheme, in many respects differing radically from the first was set out in an official memorandum with a covering letter to local authorities issued by the Minister in June of last year. We printed two articles describing and commenting on this second scheme in the *Journal* of June 11th 1927 (p. 1073) and that of July 2nd, 1927 (p. 21). The Association welcomed and gave a general approval to the first set of proposals as going a good way towards that simplification and even unification of administration in matters of health which has for so long been the policy of the Association. Two important objections in detail were however, raised that there was no compulsory co-option of medical representatives and other suitable persons on the statutory committees dealing with health matters including those transferred from Poor Law administrations and that county councils were to be given a general supervising power over and responsibility for, the administration of health services in the hands of all borough and urban district councils, within the county. We expressed profound dis-

appointment with the second set of proposals as seeming to abandon—except in county boroughs, and even there with qualifications—this main principle of unified administration. Boards of guardians were not to be abolished, then areas and methods of election were merely to be modified. Rural district councillors were to be perpetuated as ex officio guardians, and though greater freedom in the use of institutions was to be brought about, their financial and general administration was to become even more complicated than at present. These and other defects seemed to us to make the second scheme not worth having in county areas.

The third set of proposals just made public by the Minister of Health, is now placed as an integral part of the whole policy of the Government for rating and local government reform. It is intended to be judged along with the relevant proposals of this year's Budget and with the Rating and Valuation (Apportionment) Bill now before Parliament. The proposals are not final, they are presented for the information and consideration of local authorities and other bodies directly concerned therewith, and discussions between such bodies and the Ministry of Health during the next few months may be expected to result in some modifications, perhaps of considerable importance, in detail. It may be said at once, however that this third scheme, so far as it relates to Poor Law reform and consequential modifications of health administration, approximates much more closely to the first of the earlier schemes than to the second, and it will almost certainly, therefore, be found that the British Medical Association will welcome it and be in a position to give it as a whole its cordial support. The ill advised proposal of the first scheme, to which we have alluded, that county councils should have supervision of and responsibility for, the health administration of urban authorities within their area, does not appear to have any place in this third version. Boards of guardians are definitely to be abolished and their functions transferred *in toto* to county councils and county borough councils. Each county and county borough will be a complete unit, and the council of each such authority will be required to prepare, in anticipation of the date of the Act coming into operation, a scheme of the administrative arrangements which it will make for the discharge of its new functions. Every such scheme will be subject to the approval of the Ministry of Health, and before this is given there will be an opportunity for the representations of other authorities and of persons interested to be considered. It is intended that there shall be a good deal of freedom and elasticity in the formulation of these schemes, but the Parliamentary Paper gives definite indications of some of the things they should provide for and of the arrangements which would probably be favoured as convenient and proper. Much, therefore, will depend upon the action of county councils and county borough councils but if they act in accordance with the indications given, and in the spirit of the Government memorandum a great advance will have been made in the direction desired by the British Medical Association.

Three important points to which attention should be particularly directed are (1) distribution of functions (2) delegation of functions (3) co-option of members on administrative committees. In none of these directions is there to be the compulsion which the Association would have preferred, but all of them are to be within the power of the councils and the Ministry indicates that it may in most cases be desirable to adopt them. This is obviously true. For

¹ Stationery Office Cmd. 3134 1s net.

a council simply to hand over the transferred functions (apart from the power of raising a rate or of borrowing money) *en bloc* to a new committee instead of referring the health functions to its Health Committee (or Maternity and Child Welfare Committee or Mental Deficiency Committee as the case may be), the education functions to its Education Committee, and the assistance functions to another committee, would be to reduce all advantages of the reform to a minimum. Not to use the power of establishing local subcommittees for suitable areas in a large county would clearly be a mistake. Further, where in a county area there are non-county boroughs or urban districts of suitable size which are themselves authorities for health, education, maternity, and child welfare or other such purposes, it would result in a lamentable confusion and overlapping if the county council did not delegate the appropriate functions (apart perhaps from residential institutional provision) wholly to such authorities. Again, if, with all this extra work thrown upon it, a council did not utilize on its committees and subcommittees the services of interested and experienced persons, including members of the medical profession, who did not happen themselves to be members of the council, much valuable help would be wantonly lost and the work would probably be done less efficiently. It appears certain, however, that no council is to be obliged to adopt these desirable methods, and it may therefore be necessary in some cases to bring persuasion and even pressure to bear in order to secure their adoption. It may be added that it is proposed to provide that existing Poor Law officers shall be transferred to the new authorities or that proper compensation shall be paid. Some modifications of the proposals will be required in their application to London and to Scotland. In London the Metropolitan Asylums Board will cease to exist, and it is proposed that in Scotland—as in England and Wales since 1902—the separate education authorities shall also disappear, their functions being transferred to the main local government authority of the area.

Besides explaining this scheme for the reform of the Poor Law and of local health administration, the Minister's memorandum also deals with highway administration and with financial proposals with regard to rating reform and grants from the Exchequer for local services. These are, of course, of very great importance, but, though no doubt many of our readers will be interested in them, they are not the particular concern of the medical profession as such. A somewhat elaborate formula is given whereby the appointment to areas of the new and greatly increased grants in aid is to be made. This will not be fully understood by the uninitiated, but it may be of some interest to note that its main features are very similar to those of a suggestion made some fifteen years ago by Dr Brackenbury in connexion with evidence given before an interdepartmental committee on education finance. He suggested that the chief factors in such a formula should be (1) population, (2) proportion of children up to 14 years of age to total population, (3) rateable value per head of population below a certain figure, (4) in sparsely populated areas the number of persons per acre. In the formula now put forward for the wider purpose these are the factors, but the proportion of children below 5 years of age is taken instead of up to 14 years, and the sparsity is judged in reference to mileage of roads instead of acreage. There is also now added a further factor relating to the figure of unemployment in each area.

THE PSYCHOLOGY OF THE SICK

SIR FARQUHAR BUZZARD, Regius Professor of Medicine in the University of Oxford, gave an address some weeks ago to the Royal Institution on "The psychology of the sick," and the text of this has now been printed in pamphlet form. His first object was to show how great a motive all health had been behind man's desire and man's search for knowledge about himself, his structure, and his functions. It might be questioned, he said, whether mere curiosity, without the stimulus of ill health, would have afforded the necessary incentive, whether, for instance, we should not still have been ignorant of the composition and activities of the gastric juice had not indigestion marred the happiness of countless lives. Disease, indeed, had not only prompted research, but had provided man with much of the material essential for his investigations. At every step in the progress of biology careful observation and study of the abnormal had given us the means by which our conceptions of the normal could be controlled and checked. Conduct and behaviour, as the expressions of mental activity, had hitherto been regarded as the special province of the psychologist, but evidence was accumulating to show that such study must depend in the future more and more on the co-operation of workers in other branches of science. Sir Farquhar Buzzard reminded his hearers of certain salient features pertaining to the normal anatomical and physiological development of the brain and how, as in the animal scale, so in the course of the growth of each human being, a close parallel was found between the degree of development of the brain and the degree of development of intelligence or mental capacity. The newborn infant possessed a brain not only smaller but more primitive in structure than that of an adult, large numbers of the nerve elements were immature and therefore incapable of taking their part in those activities for which they were destined. The development of these elements continued far into adult life, and corresponded with the increase of knowledge and expansion of intelligence characteristic of these years. After middle age the multiplication of processes and the formation of new links between various centres gradually ceased and the mind became less and less capable of acquiring fresh knowledge or of making novel adjustments. After presenting in outline the life history of a normal human brain and a normal human mind, the lecturer went on to discuss those agencies which disturbed the stream of mental and moral progress, and later the structural changes found in the brain in association with those disturbances, illustrating and illustrating the law whereby those functions of the brain acquired most recently in time, and most highly specialized or complex in character, were the first to fail and the last to recover. Passing next to the associated psychical and physical disorders attendant upon disease, Sir Farquhar Buzzard spoke of the effects produced on the brain and mind in sufferers from encephalitis lethargica—a subject dealt with at length by Dr Allan Parsons in the report of which a notice appeared in our last issue at p. 1122. In this disease any part of the brain might be attacked, and all forms of paralysis, blindness, deafness, loss of speech, and of mental faculties were, from time to time, left in its train. One group of cases called for particular attention, a group consisting of children of school age who had been bright, well conducted, and of average ability and character, and whom this disease had left not physically impaired, but hopelessly lacking in moral sense and responsibility. After demonstrating by lantern slides the relationship between disorders of mentality and structural changes in the brain, Sir Farquhar Buzzard concluded his address by stating that the evidence drawn from pathological sources warned us that we could not remember, recognize, reason, or

express ourselves unless our brains were structurally healthy and intact, and that there were material alterations of structure, physical or chemical in origin, underlying and perhaps even determining the psychology of the sick

LINACRE'S INFLUENCE ON ENGLISH MEDICINE.

THOMAS LINACRE (1460-1524), the prototype and father of the scholar physicians in this country, exerted a lasting influence on medicine by founding the Royal College of Physicians of London in 1518, and brought the spirit of Greek learning into the intellectual life of the country. By his will he also established lectureships at the two older universities, but unfortunately these did not fulfil the intentions of the pious founder for example, at St John's College, Cambridge, the lectureship became a college appointment and largely a sinecure, twenty years ago, however, the character of the office there was changed, and a distinguished leader in medicine was appointed each year. In 1908, as the first lecturer under the new regulations, the late Sir William Osler gave an account of Thomas Linacre's life, of his activities as a medical humanist and a grammarian, and of the history of the Cambridge foundation, in 1913 the late Sir Norman Moore discoursed in his inimitable manner on "The Physician in English History," and on May 5th last Sir George Newman read an essay, both learned and delightful, on Linacre's influence on English medicine, which has just been attractively printed for private circulation as a pamphlet of 37 pages. Though the subject is much the same as Sir William Osler's it is treated on different lines, and the reader realizes that these two scholarly essays are complementary to each other. Going to Italy with a scholastic grounding in the classics Linacre brought back to England a living comprehension of the service which pure Hellenism could render to English medicine, of the essential importance of Aristotle, and of the necessity of a re-orientation of medical knowledge as transmitted by the Arabs. In conclusion, Sir George Newman points out that, although Linacre and his pupil Sir Thomas More knew that the future well-being of the English nation lay with simple methods of prevention, this practice is still widely disregarded. Readers of the author's book of essays, *The Interpreters of Nature* published last year and reviewed in our issue of April 30th, 1927 will naturally hope that in its second edition the Linacre Lecture of 1928 will be included.

MEDICINE AND FLYING

SIR SAMUEL HOARE, Secretary of State and President of the Air Council after presenting the prizes at the London Hospital Medical College and Dental School on June 29th, made some interesting remarks on the contacts between the new profession of flying and the ancient profession of medicine. He said that there was no profession in the world which demanded a higher standard of physical and nervous efficiency than flying. As the Royal Air Force had developed, the old tests which had proved sufficient for the Army and Navy were quite out-distanced, and it was soon evident that the man who had what the insurance companies would call a first-class life was by no means necessarily a good pilot. Other tests had to be superimposed, and the medical officers of the Air Force had accordingly gone to work in a special way. Instead of merely ascertaining that a candidate for a commission was free from any obvious disability or disease, they had worked out some special tests for the efficiency and co-ordination of brain, eye, hand, and foot. Sir Samuel Hoare mentioned that a short time ago he himself went through these tests, and he was glad to report that, notwithstanding five years' work in the Cabinet, his eyesight was classed in the same category as that of Mr. Jack Hobbs, the well-known professional cricketer, who had

been examined shortly before. But he was excelled by Lady Maud Hoare, who accompanied him in his flight to India and back, in respect of co-ordination of movements of hands and feet, excellences which he attributed to her habit of continual motor-driving in London. The tests applied to candidates at the medical stations were supported in a remarkable degree by reports received afterwards from the units to which the newly commissioned officers were sent. This series of tests had been developed, not from theory, but from practice. The men who had proved themselves to be the best pilots were taken and their qualities analysed, and the result of the analysis was made the standard for application to subsequent candidates. Sir Samuel Hoare pleaded that the medical services of the Air Force should be considered not only as an integral part of the 'new arm,' but as an important branch of the medical profession. He mentioned also the services which the aeroplane itself was rendering as an instrument of first aid. During some recent military operations in a difficult mountainous region of Kurdistan, about one hundred men of the regiment fell ill of dysentery. Thanks to the Royal Air Force, every one of those men was transported with the utmost swiftness to the hospital at Baghdad—an operation which otherwise than by air would have involved days of painful journeying—where they all completely recovered. One of the principal sheiks of the desert, a man who had lived his life under similar conditions to the patriarchs of the Old Testament, went down with pneumonia. An aeroplane was sent to his assistance, he, too, was conveyed to the hospital at Baghdad and made a good recovery. The aeroplane, besides being an instrument of defence and of civil transport, was specially well adapted for ambulance purposes. Some of the fastest aeroplanes were now being equipped in such a way that they could easily accommodate stretchers, and Sir Samuel Hoare said that he himself had recently flown in one of these machines a distance of two hundred miles in sixty-eight minutes.

A CAROTID RESPIRATORY REFLEX

THE exaggeration of the respiratory movements caused by pressure on the side of the neck was formerly attributed to stimulation of the vagus nerve, recent investigations, however, by Drs. D. Danileopolu, I. Marcus, G. G. Proca, and E. Manesco of Bucarest have thrown some doubt upon this explanation. In a preliminary note published last year in the *Revista Stiintelor Medicale* they ascribe this respiratory reflex to mechanical excitation of the carotid sinus. They found that this phenomenon, together with the alterations in cardiac rhythm, blood pressure, and contractility of the stomach which accompanied it, could only be produced by pressure at one spot just below the angle of the jaw. Though the pneumogastric is accessible to the finger below this spot, pressure on the lower part of the nerve did not produce the reflex effects. By means of experiments on dogs the observers satisfied themselves that the starting place of this phenomenon was the bifurcation of the common carotid artery, which corresponds with the spot just below the angle of the jaw. From their experiments these observers have arrived at some preliminary conclusions. They have found that mechanical irritation of the central end of the vagus will only produce alteration in respiration if it is exceedingly intense, and then merely to a small degree. Anatomical examination of the nerve supply of the carotid sinus, though not yet complete, has shown the presence of filaments from the superior cervical ganglion, from the upper part of the trunk of the vagus, and from the glosso-pharyngeal nerve. The area of distribution of these filaments is very susceptible to pain, even in dogs under the influence of morphine. Surrounding areas are by no means so sensitive. When the carotid

sinus was carefully exposed in morphinized dogs, pinching with the fingers readily provoked the respiratory reflex, and as the phenomenon occurred whether the common carotid were tied or not, it could have nothing to do with the cerebral circulation. The observers have convinced themselves that the reflex is started in the tunica intima of the artery, and at a particular spot in the carotid sinus. Though excitation of the sinus, either from within or without, may lead to pain, the respiratory reflex itself is not painful. In connexion with their experiments on the tunica intima study was made of the vascular depressor reflex described by Hering as being caused by mechanical irritation of the internal wall of the carotid sinus. It was found that the reflex could be conducted by a sympathetic or a parasympathetic route, with correspondingly different results, and it is proposed to term it the pressor-depressor carotid reflex. It is suggested, as a result of these investigations, that the dyspnoea of effort may have its origin in excitation of the carotid sinus region, and that there exists in the arterial tree a reflex producing zone able to regulate the cardio-vascular circulation, the functions of the respiratory centres, and possibly even other vegetative functions in the body. So far very little study has been undertaken of the relation of the reflex to pathological conditions, but the present authors have noted in an old case of encephalitis that compression of the carotid sinus produced a prolonged period of apnoea instead of the normal effect

THE NATIONAL PHYSICAL LABORATORY

SOME hundreds of visitors journeyed to Teddington on June 26th, when the National Physical Laboratory was thrown open for inspection. They were received by Sir Ernest Rutherford, chairman of the general board of the laboratory, Sir Richard Glazebrook, chairman of the executive committee, and Sir Joseph Petavel, the director, and were then allowed, under most competent directions, to wander over the laboratory. The laboratory, we may recall, is not a single building, but an estate of perhaps fifty separate buildings, divided by roads, some of which bear such names as Kelvin and Rayleigh Avenues. The work of the laboratory has often been described in these pages in connexion with the annual reports which emanate from it. It is an extraordinarily varied and impressive work, and to the man whose bent is for physics and mechanics it must offer as many exciting points as the zoological gardens to a small child. Not many of the researches which are proceeding have a bearing upon medicine. There is, of course, the routine testing of clinical thermometers and the visitors were introduced to the groups of patient ladies who are engaged upon this rather drudging toil, ascertaining and registering the accuracy of the thermometers to the number of something like two thousand a day. The testing of x-ray protective materials goes on continually, and specimens of the cements and plasters which are advised for lining the walls of x-ray cubicles and departments were on view. Other features of interest to the x-ray worker were the testing of pastilles, the experiments (still in the preliminary stage) on the ionization standard of x-ray dosage, the alpha ray testing of radioactive materials, the gamma-ray testing of radium, and some apparatus for the ready identification and measurement of radium containers. These, however, are all side-shows in comparison with the great work of the laboratory in aerodynamics, engineering, and electro-technics. The wind tunnels in the aerodynamics department, where experiments are proceeding on interference effects which have a close bearing on the control of aero planes, excited a great deal of interest, as did also the high-voltage building, with its power equipment, and the illumination building, where the efficiency of light wells

in buildings is being measured and the reflection characteristics of road materials are under investigation. The great purpose of the whole laboratory is measurement from the standardizing of wrist watches or aneroid barometers to the gauging of radio-frequencies of 50 million cycles per second.

DAWSON WILLIAMS MEMORIAL FUND

WE again remind subscribers to the Dawson Williams Memorial Fund that they are invited to attend a general meeting at the house of the Royal Society of Medicine (1, Wimpole Street, W.) on Tuesday next, July 10th, at 5.30 p.m., to hear a statement by the honorary treasurer (Sir St. Clair Thomson) and to consider the form which the memorial shall take. The recommendation of the organizing committee is that the memorial shall be a prize, to be awarded every two years or at longer intervals, for the best work which has appeared on pediatrics since the previous award. Disease in childhood was the branch of medicine which engaged Sir Dawson Williams's earliest interest, and this special interest continued right through a career which necessarily involved a close acquaintance with every side of medicine. The meeting will also consider the arrangements as to the trusteeship of the fund and the appointment of auditors. It is hoped that as many subscribers as possible will attend the meeting or make known their preference in order that the memorial may go forward with the full approval of all those whose gifts have made it possible. At the time the circulars summoning the meeting were issued the net amount to be invested stood at somewhat over £800, but it is possible that the announcement of the closing of the list on July 10th may bring forth a number of delayed contributions. Cheques should be sent to the honorary treasurer, Sir St. Clair Thomson, at 64, Wimpole Street, W., before the date of the meeting.

THE TRUDEAU MEDAL

IN connexion with the announcement in our issue of June 23rd (p. 1097) that Sir Robert Philip has been awarded the Trudeau Medal, it should have been mentioned that this medal is the gift of the American National Tuberculosis Association and was founded in memory of Edward Livingston Trudeau, its first president. This association is the largest national organization of the kind in the world and is representative of all that is most authoritative on the subject of tuberculosis in the United States. This fact still further enhances the value and importance of the award of the Trudeau Medal to the President of the British Medical Association.

WE regret to announce the death, on July 1st, in his seventieth year, of Dr. E. M. Crookshank, F.R.C.S., Professor of Comparative Pathology and Bacteriology at King's College, London, and for many years a prominent member of the Court of Governors of the Royal Veterinary College, Camden Town.

IN the Supplement this week we publish again the provisional programme for the Annual Meeting of the British Medical Association at Cardiff, with additions and corrections received up to the time of going to press. Arrangements for the scientific and clinical work of the meeting on July 25th, 26th, and 27th are now almost complete, and it will be seen from the detailed announcements under each heading that a wide range of interesting subjects of practical importance will be discussed in the eighteen sections. Members who have not yet secured rooms should read the notice about accommodation in and near Cardiff printed at p. 6.

THE PLACE OF THE VOLUNTARY HOSPITALS IN RELATION TO HEALTH SERVICES

SIR THOMAS HORDER, Bt, K C V O, M D,
F R C P,

PHYSICIAN TO ST BARTHOLOMEW'S HOSPITAL

I ASSUME that thirty five years of close and continuous association with one of the large voluntary hospitals, as physician and as teacher, has been considered to fit me for speaking on certain aspects of this difficult but important subject. I do not dispute the reasonableness of this view. A man must be obtuse indeed if he has nothing he wants to say, or no observations to make that are worth listening to, in connexion with a subject in which the institution where he has spent so much of his life is so closely involved.

But I must make it clear that there are many points in connexion with the thorny problems which face your association concerning which I cannot help you, nor am I so presumptuous as to try. Yet it was probably apparent to the council, in sending me this invitation, that the practice of medicine and the making of doctors are matters intimately bound up with the existence and with the fate of the voluntary hospital. Also that the exercise of these two functions imposes upon every thoughtful man and woman engaged in them the clear duty of associating himself with you in finding satisfactory solutions to the problems presented to you.

For many years I have been deeply impressed by the whole nexus of co-ordinated human effort represented by the institution which has, from long association, won not only my deep affection but also my utmost admiration and respect. The business acumen of its governing body, the administrative ability of its lay staff, the whole-hearted devotion of its multitude of loyal friends and supporters, the ample scope it affords for the pursuit of medical research and progress, the complete training ground it furnishes for the education of medical men and of nurses, and, finally the confidence which its prestige inspires in the hearts of its patients—all these things combine to make a large voluntary hospital a unit of singular and enormous value in the social economy.

The committee of the medical council of my hospital, appointed to consider the letter from the Ministry of Health with which we are all here now so familiar, in their report, which was sent to the governing body, proudly drew attention to the fact that St Bartholomew's Hospital is in no sense a local hospital, but rather a national institution. I would go further. I would say that St Bartholomew's, like every one of our voluntary hospitals with attached medical schools, is an international institution. This fact was demonstrated a few weeks ago, when delegates from over forty nations collected in the great hall of Harvey's hospital to do honour to his work and to his memory. And there are voluntary hospitals for the treatment of special diseases both in London and the other large centres of Britain, without schools, yet possessing great and wide reputations, partly because of the high standard of the work done in them and partly because of the distinction of members of their visiting staffs.

The Bogy of State Control

There are some who fear that the voluntary principle underlying these great institutions, and under the aegis of which so much work and progress are possible, is in danger of supersession by State control. I think this is a bogy. I find it impossible to believe that any statesman can sincerely consider such a step. Quite apart from the fact that the Minister of Health has so many irons in the fire that he is continually in danger of leaving one or two of them to get quite cold—a notoriously unpopular thing to do—and therefore has little enough room for such a large iron as this would prove to be, I credit him with too much desire for efficient medical service for the nation to wish to demolish the edifice which is, of all edifices yet built

with this purpose in view, the most efficient. That we should wish to co-ordinate the national health services seems reasonable, but to hinder his bureau by instituting State control over institutes so firmly established, and so generally acknowledged to be effective, as are the large voluntary hospitals of the country, seems to me the least likely thing to attract him.

For some time after the war the greatly increased expenditure of the voluntary hospitals certainly tended to increase the fears to which I have referred, and suggestions of State subsidies naturally furthered these fears. But that time of stress has fortunately passed and the balance sheets of most of these institutions have in recent years shown a much healthier state of affairs. It is worthy of notice in this connexion that if we consider the sources of income, this improvement is not so much the result of increased donations and subscriptions as it is of actually earned income. In the case of quite a number of the voluntary hospitals the receipts on account of services rendered actually exceeded those from voluntary gifts in the year 1926. And in one case the receipts from public authorities alone amounted to a figure much less than that from total voluntary gifts. Thus it seems clear that, in an indirect fashion, the voluntary hospitals are receiving State aid, and that to a not inconsiderable degree. In other words, they are being paid for work done a principle which must surely receive our commendation, and we may trust the public to imitate Divinity in helping those who help themselves, rather than remove its support when it discovers that the "voluntary principle" has changed somewhat in its connotation.

Centres of Health Services

And yet these fears of which I spoke have not departed, indeed, they have reemerged of late, because, in his desire to ventilate certain difficulties relating to other parts of the national health services, the Minister has, not unnaturally, cast his eye upon the voluntary hospitals, and has considered what relation they might bear to a co-ordinated scheme. But we should not, I think, read more into such a survey, or into the questionnaire which he has issued through his permanent secretary, than this. It is clear that no such scheme can possibly be considered without reference to the part that may be played by the largest and the most active units now operating in regard to the study and the treatment of disease. The chief aim of a Ministry is to foster and to encourage rather than to control. Reform of the Poor Laws and co-ordination of the health services go naturally hand in hand. In attempting these things it is a statesmanlike thing to proceed from the centre outwards. The centre is the voluntary hospital system, and the Minister begins by inquiring to what extent and in what manner he may expect help from this quarter. This is how the present position appeals to me.

We cannot, any one of us individually, decide upon the degree to which co-ordination is necessary, since conditions vary so much in different places. The Minister of Health and his chief officers are alone able to say how much need there is for fresh organization, for they alone are able to visualize the whole position. By its regional committees, however, the British Hospitals Association should also be cognisant, to a very large extent, of the gaps and the overlapping in various areas. The association can therefore render valuable aid to the Minister in this respect.

There are some reforms which make an appeal to all of us. Of the alleged shortage of beds in the voluntary hospitals I am not very competent to speak. But that the large number of beds in the Poor Law infirmaries should be more efficiently utilized, and should receive more definite and more systematic medical supervision, is clearly desirable. Neither destitution nor senility should constitute a bar to thorough medical treatment. Nor should they of themselves qualify for beds that are badly wanted for sick persons. A revision of the Poor Law infirmary wards might well lead to the utilization of some of the beds, in close association with the voluntary hospital of the area concerned, thus allowing of a natural expansion of the voluntary hospital without incurring heavy additional capital expense. Certain types of case might with advantage be drafted into these remodelled Poor Law

wards, such as cases of inoperable cancer, of chronic diseases of the heart and kidneys, and of chronic arthritis. To the advantage of such an arrangement in relation to medical research, and to medical education, I shall refer later.

Problems in Country Districts

In London and the large centres the question of overlapping, with consequent duplication of effort and wastage of material, scarcely arises, but this is no doubt an urgent problem in the country districts. How best to deal with it lies outside my special knowledge. This is an example of the fact that we are not faced with one inclusive problem but with many different problems. Indeed, each area has its own problems and each area is best competent to solve its own problems. Two great principles, it seems to me, should guide us. So far as London and the other great centres are concerned we should not consider decentralization a deterrent to progress, but rather a stimulus to it. So far as the country areas are concerned, combination and co-ordination are the great needs. These two processes are mutually complementary and the operation of them, conducted skilfully and with foresight, should effect solutions to most if not all, the problems that arise.

Perhaps one of the most urgent of all our problems is the provision of adequate medical and surgical treatment for middle-class patients of limited means. This is a crying need. We in London have no alternative between the general wards of a large hospital and a private nursing home where, often enough, the cost to the patient is absolutely prohibitive. In other large centres the state of affairs is much the same. In the country districts these patients are often better catered for, many cottage hospitals having a few small rooms where such persons can be treated for reasonable fees. It should be a *sine qua non* in the reconstruction of every large hospital that an annex for "paying patients" is included in the lay-out. Administered with the same business ability shown in running the general wards such annexes might be made to pay a handsome sum annually to the hospital exchequer. Here is a reform that can be proceeded with at once, without waiting for Poor Law reform to give the voluntary hospitals power to act.

There is also need for considerable extension of the convalescent homes in connexion with the large voluntary hospitals, but the patients at these homes should be under fuller medical supervision. This would admit of a quicker turnover of cases in the parent hospital, where many patients are kept during the convalescent stage of their disease, thus blocking the beds for more acute cases. The system of pooling the beds at these homes seems, for reasons that are obscure to me, to be much less in operation than I should think possible and desirable.

Health Services and Medical Education

When I said, at the beginning of my remarks, that the problems of co-ordination of the health services have a bearing upon medical education, I had in mind the extra teaching facilities that such co-ordination would yield at all periods of the doctor's career. There are three such periods in medical education, and at each period the voluntary hospital has, up till now, provided almost entirely the material and the opportunities for the medical man's training. There is the education of the student prior to his qualification, there is the valuable experience which he gains by holding a resident staff appointment immediately after qualification, and there are the "refresher" classes and demonstrations which are so essential to the maintenance of his efficiency after he gets into practice, and which are summed up in the term "post-graduate" medical education.

It may be thought that during the first of these periods further co-ordination of the health services offers very little by way of extra facilities to the medical student's training. But this thought is superficial. It is quite true that this is a period of intensive culture, and that the time of the embryo doctor is very largely taken up at the centre of tuition, which is his medical school and hospital. But even at this stage the sphere of his education might be enlarged profitably if some of the ideas recently mooted were brought

into effect. All the obstetric, and even much of the gynecological, practice might go on in certain wards in municipal hospitals, and thus offer a good field for teaching. The same principle might apply to certain plastic operations, as for hernia—for which, by the way, there is said to be a definite shortage of beds in the voluntary hospitals. Again, what could be more useful to the student than a series of demonstrations upon the diseases and disabilities of old age? And where could anything like such good material be found for this purpose as in the Poor Law infirmaries? The types of clinical material which would be rendered available for tuition in the municipal hospitals might easily be amplified, so that, just as the medical student in London has, for some time past, gone to hospitals under the Metropolitan Asylums Board for special instruction in fevers and in lunacy, so he will, perhaps, in the future go to similar institutions for other, and equally important, branches of his study.

More Resident Appointments

When we turn to the second stage in the doctor's training—the preparation of the qualified medical man for more efficient practice than his mere diploma gives him—we can visualize under a co-ordinated scheme, a much larger number of house appointments, whether resident or not, than is now open to him. The value of these would be quite incalculable. It is my lot to meet many practitioners up and down the country and to discuss their patients with them. The difference in efficiency between those who have, and those who have not, had the immense advantage of holding house appointments is very striking, so much so that it is not very difficult to grade these colleagues according to this very point. Close contact with hospital management, the sense of responsibility, the daily intercourse with their seniors, the discussions with their fellow-residents, the conduct of emergencies—these are some of the great benefits which the holding of such a post as house-physician, house-surgeon, or resident medical officer confers, and which helps to make the doctor competent, reliable, and tactful when he comes to engage in actual practice. Any organization of the health services which multiplies these posts, whether in the large centres or in country areas, would add greatly to the total efficiency of medical practice.

But it is probably in the third stage of medical education, that of post-graduate tuition, where we may foresee the greatest good to ensue from a well-planned scheme of hospital co-ordination. And this applies, as in the second stage, both to the centres and to the country districts.

The seemingly indefinite postponement of a large and adequate system of post-graduate education in this country is, to my thinking, a matter for grave concern, and the present hold up of the scheme when had been evolved as the result of the work of the Departmental Committee of the Ministry is a source of great personal regret. That London, the centre of a great empire, should still lack such a scheme *in esse* is an astounding anomaly. There are tears for these things, but I must not depress you to-day, you have troubles enough of your own!

Post-graduate Study Facilities

Assuming that we do some day get seriously to work on the matter, it is generally agreed, following the work of the Athlone Committee that a complete post-graduate clinical unit or hospital is essential, since the segregation of post-graduates from undergraduates seems imperative to a successful scheme. The linking up of such a unit with certain of the Poor Law hospitals would provide excellent facilities for post-graduate education, and the staffing, the pathological investigations, and the operative work might well be undertaken by the central post-graduate institution. Following such an institution in London would naturally come affiliated post-graduate hospitals in other large centres. The present tendency towards the introduction of an earlier retiring age for members of the staff at the undergraduate teaching hospitals flies a number of men who have had great experience in medical education and practice for engaging in just this class of work, and a panel of such teachers would

be available both for the central institutions and for travelling to the smaller areas, where a rota of lecturers and demonstrators might be in operation. In most of the large provincial towns, again, there are senior men with considerable hospital experience who could do valuable work of this kind, given that the clinical material were properly assembled. Thus there would come into existence teaching centres of sufficient size and importance to enable practitioners to engage in post-graduate study within their own areas, and thus the necessity of leaving their practice in order to live for a time in London, or some large but remote academic centre, would be obviated. These facilities would be of inestimable service to the panel practitioner, who is too often blamed for not being "up to date," yet has no organized means at present of escaping such censure. Post-graduate instruction is, after all, a duty which the Ministry owes to those doctors whom it employs under the National Health Insurance Acts.

Research in connexion with the causation of disease, and especially in connexion with treatment, would be greatly aided by such segregation of cases as has been suggested in considering the revision of the Poor Law hospitals and the placing of the beds in these institutions under the aegis of the large voluntary hospitals. Comparative methods of treatment in such diseases, for example, as inoperable cancer, can only be undertaken with scientific method where a number of similar cases are assembled in one institution. Similarly, a ward given up to arthritis would allow of that team work which is notoriously desirable in the investigation and in the treatment of such a disease. Time prevents me from enlarging upon this aspect of the question.

And now, in conclusion, let us assume that a definite position is really created by the questionnaire issued by the Ministry, and that the replies of the voluntary hospitals are seriously awaited and will be as seriously considered. Then I submit that they have here a great opportunity. I suggest that they approach it not only carefully and, if you like, cautiously, but with enthusiasm. Let them demonstrate their recognized supremacy by an active and progressive spirit, and a willingness to co-operate in any forward move on the part of the Ministry. They are to-day the centre and focus of medical science and of medical art. In proportion as they are these they have a duty in connexion with every advance that is suggested, whether in the direct transmission of knowledge and administrative experience or in any co-ordination of the health services which may be desirable in the national interest. Within the walls of the voluntary hospital resides a large mass of potential energy of a very high order, and this energy should be at the service of the State if, and when, it is required. The infusion by this energy of outlying units is a process which should commend itself to all of us, since the result would inevitably mean the raising of the general level of the health services. There should be a constant stream of influence from the centre to the periphery, so that only the inevitable barriers of place and time—and these barriers become less and less with the years—should determine that John Jones in the Poor Law infirmary, or in the cottage hospital, receives less skilful treatment for his disease than does Thomas Smith in the wards of the institutions of which we are justly so proud.

But perhaps the interest of the Ministry in our answers to its questions has already subsided, the Minister's scheme of Poor Law reform having received a serious check in deference to the larger projects of his more ambitious colleague. Or perhaps another Minister will shortly sit in his place to whom the zeal for organization may not make the same appeal. I still hold that our better attitude is one of advance rather than of standing still in these matters. I think the recent stirring of the waters has been for the public good, and I suggest that we each and severally busy ourselves in doing our utmost to co-ordinate the health services by any means in our power. I feel confident that any move we ourselves make in this direction will receive sanction from the Ministry if only it spells greater efficiency and a wider application of the knowledge we possess. It is only by such advances that the voluntary hospitals can hope to maintain their

present position in the confidence of the public as the responsible bodies to whom it looks for guidance and control.

I find, indeed, that your Association is pledged to just such activity as I am now advocating, for in the statement of its policy there occur these words:

'The voluntary hospitals should be ready to fulfil their proper functions in relation to all the other agencies, State, municipal, or voluntary, concerned with the general health of the community.'

I feel sure that the spirit of this readiness to function in this particular direction is intended to be active and not passive. How much of such activity is practicable, and in what directions it can be exercised, can only be determined by energetic but tactful approaches to the various authorities concerned.

EPSOM COLLEGE

THE seventy-fifth annual general meeting of the Governors of Epsom College was held at 49, Bedford Square, W.C., on June 28th, when Dr. Raymond Crawford was in the chair.

THE CHAIRMAN, in proposing the adoption of the annual report, referred to the progress of the fund for the new sanatorium, of which outline plans, together with full details as to the accommodation to be provided, were published in the *British Medical Journal* of December 3rd, 1927. He pointed out that if two sums of £5,000 were received the council could put the work in hand, as the total sum collected to date amounted to nearly £5,000. The College would benefit in another direction by the provision of the new building, because the old sanatorium could be easily adapted for the admission of about forty more boarders. The enlargement of the school in this way would result in many economies, and the further increase in income would enable the council to improve the salaries paid to the masters. The report was adopted.

Dr. F. W. Collinson and Dr. R. W. Innes Smith were elected vice-presidents of the College in recognition of their valued services, each having collected over £1,000 as an honorary local secretary.

A new by-law and various alterations in the existing by-laws were confirmed, including changes made as a result of the council's decision to abolish the Lower School and to raise the age of candidates for Foundation scholarships.

The scrutineers announced the result of the voting as follows:

Honorary Pensionerships (£75 a year)		Votes.
Dr. James S. Robertson		4,157
Mrs. Gertrude Middlemist		3,326
Mrs. Elizabeth Christian		2,485
Mrs. Mary G. S. Kenny		2,086
Ordinary Pensioners (£50 a year) with an addition of £10 a year from the Dr. Strong Fund		
Mrs. Ellen M. Blake		2,067
Dr. Lambert Houghton		2,012
Mrs. Ida M. S. Style		1,672
Dr. Vincent O. Taylor		1,634
Pugh Pension (£40 a year)		
Mrs. Mary A. Ingledew		1,481
Broadwell Sewell Annuitants (£30 a year)		
Miss Ella M. Lenev		2,631
Miss Elizabeth E. B. Diller		1,793
Foundation Scholars		
Alfred G. Stansfeld		17,657
Geoffrey G. Wallis		13,079
John R. Copeland		11,042
John A. H. Holburn		10,757
John Watson		10,496
Antony L. Haynes		10,427
Louis C. Dillon		8,651
Eric J. Holborow		6,531

THE SECRETARY mentioned that Mrs. Fliza M. Morrison, Dr. Theodore M. Kendall, and Mrs. Lillian Marshall would be appointed ordinary pensioners under By-law 16 at the council meeting which would be held immediately after the annual general meeting, further vacancies having arisen.

A vote of thanks to the Chairman was adopted with acclamation on the motion of Sir John Broadbent, who referred to the many constructive suggestions for the improvement of the College which Dr. Crawford had cordially supported.

SOMETHING NEW IN MEDICAL DEFENCE

INDIVIDUAL medical defence is not provided by the British Medical Association, since this is outside its legal powers. Every medical practitioner is, however, advised by the Association to join one of the recognized medical defence societies immediately upon registration. This advice is given with every possible emphasis in the Association's *Handbook for Recently Qualified Medical Practitioners*, and is repeated year by year in the Educational Number of the *British Medical Journal*. Particulars of the three well established professional bodies, which for a small yearly sum undertake the legal defence of their members, are given in the *Handbook*. Their names are the Medical Defence Union Ltd., the London and Counties Medical Protection Society, Ltd (both with offices in London), and the Medical and Dental Defence Union of Scotland, Ltd (with offices in Glasgow).

It appears that a fourth body has now been formed to undertake the same kind of work under the personal direction of Mr William Findlay, formerly secretary and treasurer of the Medical and Dental Defence Union of Scotland. According to the printed circulars, this new competitor in a field already well covered is styled "The Surgical and Medical Protection Union of London, Ltd," having registered offices in London and a "Department for Scotland" in Glasgow. The particulars filed at Somerset House show that the company was registered on April 13th, 1928, with a nominal capital of £15,000, the shareholders and directors being Mr W Findlay and Mr A McClure solicitors. No provision is made for the appointment of a council or for any representation of members or subscribers either in the management of the company's affairs or in the direction of its policy. It is in fact a proprietary concern owned and managed by two non-medical persons. The circular letter inviting the adhesion of members of the medical profession states that "the annual subscription is £1 per annum, and to practitioners who are transferring from another Defence Society the subscription is 15s, and will be retained at that sum for at least three years. No entrance fee is payable on admission. The subscription includes an insurance, unlimited in amount, and all costs, in cases which may be raised against a subscriber, in which he may be found liable in damages." As a further attraction the directors of the company pledge themselves to defend subscribers "against all claims which may be made against them, in respect of their professional work, including liability not only for the acts of the subscriber himself, but of all assistants and dispensers in his employment, and of other practitioners acting on his behalf." Moreover, according to the memorandum and articles of association, these benefits are to be extended not only to registered medical practitioners, dental surgeons, and veterinary surgeons, but also to nurses, proprietors of nursing homes, etc., and all other persons or institutions having for one or more of their objects the cure of physical or mental disease.

We are informed that Messrs Findlay and McClure and Co., on behalf of this new body which they have founded, recently circularized the members of the Medical and Dental Defence Union of Scotland offering to acquire the whole assets and undertaking of the Union for £10,100, and to enrol its members at an annual subscription of 15s, including an insurance, unlimited in amount, against all professional responsibility, with "an unqualified guarantee" that every subscriber will be defended "without any discretionary power to refuse defence, and, if damages are awarded that these will be paid unconditionally, as well as all costs awarded to claimants." A special general meeting of the Medical and Dental Defence Union of Scotland, attended by some 300 members, was called to

consider this matter on June 13th, and unanimously rejected the offer. We are not surprised.

It does not appear that Mr Findlay and his co-director have so far offered to buy up the Medical Defence Union or the London and Counties Medical Protection Society, but have contented themselves with the general statement that the subscription to their union is 15s to practitioners who transfer from another defence society. We anticipate that few members of these societies will be tempted to forsake the substance for the shadow.

England and Wales.

Dinner to Sir Robert Jones

ON June 28th, at the Cafe Royal, London, a group of surgeons—friends, colleagues, and pupils—entertained Sir Robert Jones to dinner. A book, specially written for the occasion and entitled *The Robert Jones Birthday Volume*, was presented to him. This book comprises a collection of surgical essays. After the loyal toast had been honoured the health of the guest was proposed by the chairman, Sir Berkeley Moynihan, President of the Royal College of Surgeons of England, in a speech distinguished alike by its brilliance and its affectionate intimacy. Sir Robert Jones replied in a charming and characteristic speech. As an indication of the feelings which prompted this tribute we cannot do better than quote from the preface of the volume Sir Berkeley Moynihan's actual words.

"This volume written by a band of brothers, is dedicated with greatest respect and with warmest affection to Sir Robert Jones on the occasion of the seventieth anniversary of his birth."

"The opportunity to pay tribute to our friend in whom we recognize one of the masters of surgery was most eagerly welcomed. We felt that it gave us the chance to say openly what has long been in our hearts in regard to his work for our profession and in acknowledgement of the inspiration, encouragement and example he has given to all who have had the high privilege of association with him."

All those who contribute to this volume are proud to think that the influence of Robert Jones of his methods and of his teaching has inspired them has found a place in their work to be transmitted by them to due course to their successors. Spirit alone is immortal. In the practice of orthopaedic surgery the spirit of Robert Jones will live for ever.

The story of the triumphs of Robert Jones as prophet, high priest, and practitioner in orthopaedic surgery makes plain the reason for our deep respect. Our affection for him transcends if it be possible our gratitude for his professional worthiness. Few men have ever possessed in so radiant a degree the genius for friendship. No one can be long in his company, none can work with him or play with him without realizing not only the sweet simplicity of his character but the greatness of his heart. He speaks ill of no man. He seeks and finds good in all things and in all men. He sets an ideal and a standard of action in friendship which all strive to reach when with him. In a long and very intimate friendship I have never heard an unjust criticism, a cruel jibe or a word of bitter cynicism on his lips. He covers his displeasure or stern disapproval by silence, or a restrained reproof that is often weightier than a torrent of words from others. His personality radiates cheerfulness, good temper and goodwill. All men are attracted by him and in war time conflicting temperaments found in him something that appeased their differences, assuaged animosities and encouraged a desire for friendliness. He was then called upon to rule in various places over colleagues at first unfriendly, openly antagonistic, indifferent to his rule or incredulous of his practice. We were all amazed at his success in overcoming very real difficulties by gentleness, sympathy, a true understanding of the minds of others and a tactfulness which in times of crisis was almost magical.

To Robert Jones great surgeon, inspiring teacher, loyal colleague, and good friend we affectionately inscribe this volume.

In addition to Sir Robert's daughter and son-in-law, Mr and Mrs Frederick Watson, and his son and daughter-in-law Mr and Mrs Arthur Probyn Jones, the following were present: Sir Berkeley Moynihan, Sir Harold Stiles, Sir John Lynn-Thomas, Mr E Munhead Little, Professor Munk Jansen, Mr A B Mitchell, Mr Thurstan Holland, Sir William de Courcy Wheeler, Mr E Lanning Evans,

Mr H A T Fairbank, Mr E W Hey Groves, Mr R O Plushie, Mr A S Blundell Bankart, Mr W Rowley Bristow, Mr Naughton Dunn, Mr G R Girdlestone, Mr Harry Platt, Mr D McCrae Aitken, Mr W H Titchoway, Mr T P McMurray

Radium Treatment at University College Hospital

The fifth annual report of Mr N Asherson, the Harker-Smith registrar, deals with all cases treated with radium at University College Hospital, with the exception of rodent ulcer, from November 1st, 1926, to October 31st, 1927, and includes a report of the subsequent histories of cases recorded by previous registrars. During the year under review a new departure was the adoption of metallic radium as the standard of measurement of dosage. All gynaecological patients treated with radium at this hospital are first examined under general anaesthesia. In the case of non-malignant or doubtfully malignant diseases the uterus is curetted and a portion of the lesion or scrapings is examined microscopically. The Harker-Smith records thus include a statement of the microscopical findings in all cases treated with radium. During the six years since the institution of this form of treatment at University College Hospital the number of cases dealt with has been as follows: carcinoma of the cervix, 118, menopausal menorrhagia, 68, fibroids, 61, carcinoma of the uterine body, 18, essential menorrhagia, 17, cervicitis, 10, dysmenorrhoea, 8, and endometrioma, 1. A summary of these cases under the respective headings is given, including an account of the subsequent progress. Among the conclusions drawn is a general impression that, as regards carcinoma of the cervix, radium seems to stop the advance of the disease locally, any extension being slow. Although in many instances the pelvis contained large growths, metastases were not clinically detectable in the liver or elsewhere in the abdominal cavity, apart from pelvic glandular deposits. Radium appeared to be definitely beneficial in the treatment of intractable menorrhagia not due to the menopause and unassociated with pelvic abnormality. All the patients with dysmenorrhoea were apparently cured. The use of radium therapy in non-malignant conditions is being extended, and cases of deafness due to catarrhal otitis media are being treated by small doses.

The Medical Superintendent of Maudsley Hospital

When, in 1922, the name of Dr Edward Mapother was submitted for appointment as the first medical superintendent of Maudsley Hospital, the condition was laid down that the appointment should be held subject to the pleasure of the London County Council, and Dr Mapother, as well as the other candidates, were informed that the Council would probably exercise its pleasure at the expiration of six years at latest. Dr Mapother has now completed his six years of service, and the Mental Hospitals Committee of the Council has reviewed the appointment. Its report is to the effect that the work which is carried on at the hospital, the first of its kind to be established, and possessing a number of special features, is still in process of development, and that the development has reached its present stage under the guidance and largely as the result of the energy and high ability of Dr Mapother. The committee has therefore come to the conclusion that it is essential for the full realization of the purposes of Maudsley that its present direction should continue, and that it would be undesirable for the Council to exercise its discretionary power to determine the appointment at the expiration of the six years' tenure of office.

London Mental Hospitals.

In November last an arrangement was authorized for the services of consultants on the staff of London Hospital and Guy's Hospital to be available for Clapham and Bexley Mental Hospitals respectively, at an honorarium of £4 14s a visit, subject to the total expenditure during any year being limited to £200 at each hospital. The Mental Hospitals Committee of the London County Council now proposes that arrangements of a similar kind shall be made for the services of consultants on the staff of University College Hospital to be available for Long Grove Mental Hos-

pital and the Enell Colony. The consultants proposed are a physician, a surgeon, an ophthalmologist, an ear, nose, and throat surgeon, and a gynaecologist. Arrangements were also made last year for one assistant medical officer in the mental hospital service to be placed at the disposal of the Minister of Health for special work at Horton Mental Hospital in connexion with the malarial therapy of general paralysis of the insane. The Ministry of Health has now asked that, pending some plan of a permanent character being devised for the carrying out of the work in question, the existing arrangement may be extended until March 31st, 1929.

Royal Sanitary Institute

The retirement of the secretary and director of the Royal Sanitary Institute, Mr E White Wallis, O B E, was made the occasion of a complimentary dinner at the Cafe Royal on June 27th. A gathering of about one hundred, including many medical officers of health, assembled under the chairmanship of Professor A Bostock Hill, M D. The Duke of Northumberland, president of the Institute, was to have presided, but was prevented by illness from attending. Professor Bostock Hill, in proposing the health of the guest, said that Mr White Wallis was appointed secretary of the Institute in 1880, at a time when the Institute was only four years old, and had a membership of little more than 300, whereas to-day it had 4,700 members on its roll. Mr White Wallis had been largely responsible for the establishment of branches of the Institute overseas and for the introduction of the Institute's system of examinations for sanitary officers into the Dominions and Colonies. He had also trained a staff in his own singularly efficient methods of secretaryship, and this fact caused the council to regard his retirement with more equanimity, though with no less regret. Sir Arthur Newsholme and Dr Charles Porter added brief tributes to Mr White Wallis's genius in affairs, his astute management of a varied team, and especially his skill in handling the arrangements for a long series of successful annual congresses in provincial towns. The chairman then, in the name of many subscribers, presented Mr White Wallis with a wireless set and a cheque. The recipient suitably acknowledged the gift and recalled some of the outstanding changes, events, and personalities with which he had been brought into contact during his secretaryship. He counted it a matter of special pride to have served the Institute while three sovereigns had been its patrons and three Dukes of Northumberland its presidents. The Institute was unique in its happy combination of several professions and interests, and this gave a never-ending variety and stimulus to its work. The only other toast was that of "The Chairman," the proposer, Mr John D Watson, emphasizing the value of Professor Bostock's Hill's thirty-five years of service on the council and committees of the Institute.

Open-air School for Bermondsey

The Nightingale House Open-air School, established by the London County Council in Fort Road, Bermondsey, was opened on June 29th by Dr F Barrie Lambert, chairman of the Special Services Subcommittee. The new school provides accommodation for 125 children. It is one of the two additional schools for tuberculous children which were included in the programme of educational development. The cost of the school, including furnishing, has been about £7,500. It stands in one acre of ground, which has been laid out by the Parks Department, and gardening will be one of the subjects of the curriculum. The buildings consist of an administrative block, open air dining room, and rest shed, and five open-air shelters of the latest type. The school will work in close co-operation with the Bermondsey Tuberculosis Dispensary, the tuberculosis officer for the borough having been appointed medical officer, and a part-time nurse from the dispensary will attend. The temperatures of the children will be taken daily, rest periods observed, and regular meals provided, for which the parents will pay if they are able. The children can be required to remain at school until they are 16. They will, however, be specially examined at the age of 14, and, if fit, allowed to leave school and enter suitable employment.

Scotland.

Scottish Graduation Ceremonies

A GRADUATION ceremony took place at Edinburgh University on June 28th, when several eminent members of the medical profession received the honorary degree of Doctor of Laws. Among those accorded this distinction were Sir John Rose Bradford, KCMC, MD, President of the Royal College of Physicians of London, Professor J. Cossar Iwart, MD, FRS, emeritus professor of natural history in the University of Edinburgh, James Haig Ferguson, MD, late gynaecologist to the Royal Infirmary of Edinburgh, R. A. Fleming, MA, MD, President of the Royal College of Physicians of Edinburgh, G. Lovell Gulland, CMG, MD, late professor of medicine in the University of Edinburgh, Dame Mary Scharlieb, DBE, MD, president of the School of Medicine for Women, London and Mr. Henry S. Wellcome, founder of the research laboratories at Gordon College, Khartoum, the Bureau of Scientific Research, London, and the Museum of Historical Medicine, London. A graduation ceremony took place also at St. Andrews University on June 28th, when the members of the medical profession who received the degree of LL.D. were Professor L. P. Cuthbert of the chair of chemical physiology in the University of Glasgow, and Professor William Darroch of Columbia University, New York, who did important work as a surgeon with the 51st Division in the great war. On the occasion of the installation of the new Chancellor of the University of Aberdeen on July 3rd the honorary degree of LL.D. was conferred on emeritus professor J. A. MacWilliam, MD, FRS.

New St. Andrews Professor

The Court of the University of St. Andrews has appointed Professor John McGibbon, MB, FRCPI, to succeed Professor Kynoch, who recently resigned the chair of midwifery and gynaecology. Professor McGibbon has also been appointed by the directors of the Royal Infirmary, Dundee, to be a medical officer in charge of obstetrics and gynaecology in the Infirmary. He graduated in medicine at Edinburgh in 1898 and became a fellow of the Royal College of Physicians of Edinburgh in 1912. He succeeded his father in a well-established practice in the Stockbridge district of Edinburgh but immediately after graduation began to devote himself specially to obstetric work. For some years he was a lecturer in midwifery and gynaecology in the School of Medicine of the Royal Colleges at Edinburgh, and acted as assistant to the late Dr. Haultain on the staff of the Hospital for Women at Viehbald Place, Edinburgh, in the establishment of which he had taken a great interest. He was also for a number of years assistant physician on the staff of the Royal Maternity and Simpson Memorial Hospital at Edinburgh, and lecturer on clinical midwifery to the University. In 1922 he was appointed professor of obstetrics in the University of Johannesburg, a post which he held till his appointment at St. Andrews University. He has contributed numerous papers to the literature of the branch of medicine in which he is specially interested, and during the past six years he has been actively engaged in the organization of the department of obstetrics and gynaecology in the University and in the Hospital for Women at Johannesburg. At one time he was examiner in midwifery in the University of Aberdeen, and for the past six years has been examiner in midwifery and gynaecology to the University of Cape Town. He is expected to take up duty at the Royal Infirmary and Medical School, Dundee, in October of the present year, when the winter session commences.

Increase of Sickness Benefit in Scotland

At the Scottish Conference of Friendly and Approved Societies, held in Edinburgh on June 23rd, Dr. G. M. Cullen of the Scottish Board of Health, speaking on the subject of medical certification under the National Insurance Act, said that the friendly societies had pointed the way which was afterwards taken by the Government and had very largely constructed the road on which national

insurance had become possible. Most doctors, he thought, had changed their minds in regard to national health insurance since the introduction of the Act. Within the past few years, however, a danger had appeared in the shape of lax certification, which must be carefully considered lest it should become a serious handicap to future administration. There was no doubt, so far as the general population of the country was concerned, that the mortality rate was lower and that so far as could be judged illness was less frequent and less severe. In respect of this, however, the amount spent in Scotland upon sickness and disablement benefit had risen from £1,570,000 in 1925 to £1,940,000 in 1926, and £2,020,000 in 1927. Some societies were giving a larger weekly benefit than previously, but it was the general opinion that the real cause of the increase was lax certification. In the speaker's opinion three factors should be kept in view when trying to reduce such laxity—namely, the insured person, the doctor, and the approved society. There was a certain impression in the mind of insured persons regarding their right to money under the Insurance Act, and approved societies might do something to spread among insured persons a clearer idea of what their privileges were. With regard to the doctors, he did not think that any layman had any idea of the difficulties of certification. Some people were unwell all their lives and yet continued to work, while others would cease work for two or three weeks because of a condition of health which was no worse than the condition of the first class he had mentioned. The question of the will to work was just as important as the physical condition. There had been lax certification from the beginning and there always would be, but it ought to be kept within reasonable bounds. Some doctors were not sufficiently careful, and possibly the imposition of a severe penalty might be advisable. Dr. Cullen thought, however, that such doctors formed a small number and the difficulty would not be properly met by blaming the doctors alone. He believed that something might be done by increasing the number of visiting nurses, and societies might combine to arrange that the certificates were supervised by some skilled person. Dr. Cullen also made a plea for more extended use of the medical referees. Sir James Ilesman gave an address reviewing the year 1927 which, he said, had not been bad from the point of view of health. The death rate, which was one great test in vital statistics, was 13.5 per 1,000 and almost at its lowest. The tuberculosis rate was stationary. A sinister shadow, however, was the mortality from malignant diseases, which was the highest on record, both in numbers and in rate. Heart disease still accounted for nearly 8,000 deaths in Scotland, malignant disease nearly 7,000, apoplexy 6,000, pneumonia nearly 6,000 and bronchitis nearly 4,000. One of the disturbing outbreaks of the year had been influenza. Unemployment still remained high, though not so high as in former years, but it affected certain areas, such as those of the coal, steel, iron, shipbuilding, and, in some respects, the textile industries. Sir James thought that the Poor Law and labour exchange authorities were tightening up administration with a view to saving as much public money as possible, and he did not criticize that, though he had been seriously disturbed by experience of the national health insurance scheme during the past two years. The year 1926 was thoroughly bad—the expenditure being 20 per cent above that of the previous year, the expenditure so far for the present year was 25 or 26 per cent above that of 1925. They were actually at the present time spending more in sickness and disablement benefit by about 8 per cent than had been calculated and in Scotland the expenditure in this respect had practically doubled within four years. This meant practically for the great majority of societies that no additional benefits could be paid, and some would only be able to provide the ordinary benefits by falling back on previous accumulations. They had to face the disagreeable possibility that a considerable number of claims were being made that were not genuine. Were the societies examining the claims with due care and capacity, and were the doctors certifying carefully and properly? Many doctors were not lax, but a minority, particularly in industrial areas, were less satisfactory. In Northern Ireland, where the experience had also been very

bad, nine doctors had been removed from the certifying panel within the last four months, and the example might have to be followed in Scotland. The administrators of the Insurance Act did not wish that any good claim should be disowned or not paid, even if by doing so a society should be put on the wrong side financially. They were bound, however, as trustees, to refuse bad claims, and Sir James hoped that in Scotland there was sufficient knowledge and sense, as well as character, to keep the scheme right and to stop leakage.

Fees under the Midwives and Maternity Homes Act

The Scottish Board of Health has issued a circular relating to a revised scale of fees for medical practitioners called in by midwives in cases of emergency in accordance with the Midwives (Scotland) Act, 1915, and for doctors attending women in childbirth under the Midwives and Maternity Homes (Scotland) Act, 1927. The fee for all attendances during confinement, including subsequent visits during the first ten days, is two guineas, and for a second doctor to give an anaesthetic, one guinea. The fee for various minor operative procedures during this period is one guinea but this is not available when the sum of two guineas is already payable. The fee in connexion with a miscarriage, including ten days' attendance, is one guinea. For any subsequent visit to the mother or child a fee of 5s. is chargeable for the first visit and 3s. 6d. for following visits, with double fee during the night. No fee is to be paid by the local supervising authority in cases where the patient is being attended under arrangements with some club or other association, or when the doctor is under obligation to treat the patient under the National Health Insurance Act, or where he is in receipt of a fee from the patient already. With regard to services after the tenth day, the fee is only paid if the doctor has reported to the local authority that he considers his further attendance necessary and submits his claim within two months from the date of the last visit covered by the scale.

Correspondence.

DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL

SIR,—Owing to the lamented death of Dr J. A. Macdonald of Tannaton, and to the resignation of Sir Robert Bolam (who has been appointed representative for the University of Durham), there will be, in October, an election of two Direct Representatives on the General Medical Council by the medical practitioners of England and Wales. It is understood that meetings of the profession will shortly be called in all parts of the country to consider nominations for such representatives.

The educational side of the Council's work is well cared for by the representatives of the various universities and licensing bodies. Many of these representatives, too, are thoroughly conversant with the special problems of consultant practice, being themselves actively working in that sphere.

Only two general practitioners at the moment have seats on the General Medical Council. The penal cases, which absorb so large a proportion of the Council's time, deal often with situations arising in the lives of general practitioners, as is only natural seeing that general practitioners constitute the bulk of the profession. The preparation of the medical student for ordinary family practice demands emphasis in the regulations laid down for his education, and for this the advice of general practitioners ought to be useful.

We are advised of a strong feeling that opportunity should be taken of this by-election to place upon the General Medical Council two Direct Representatives who have the closest possible touch with the problems and difficulties of the general medical practitioner. Having been approached on the matter, we venture to solicit the support of the profession as two general practitioners representing industrial and rural areas respectively. We are both in the active pursuit of our profession, and have had a good deal of experience of administrative and

medico-political work, which we hope would be of value if the profession should see fit to endorse our candidature. One of us (J. W. Bone) has had thirty-two years in general practice, private and contract, in the industrial area of Luton, has served on the Insurance Acts Committee for five years, and at the present time has the honour to be a member of the Council of the British Medical Association and chairman of its Medico-Political Committee. The other (E. K. Le Fleming) is familiar with other aspects of private and contract practice through twenty-seven years' work in the rural area of Wimborne, whilst in addition to serving on the Council of the British Medical Association and the Insurance Acts Committee he has been honoured by the confidence of the insurance practitioners for the past five years as chairman of the Conference of Local Medical and Panel Committees of the United Kingdom.

Our experience in interpreting the collective views of our fellow practitioners and our willingness to devote whatever time and energy may be necessary to the proper fulfilment of the duties of a Direct Representative embolden us to solicit the support of the profession generally.—We are, etc.,

June 27th

JOHN W. BONE
E. K. LE FLEMING

PROTECTION OF THE MEDICAL PRACTITIONER SIGNING LUNACY CERTIFICATES

SIR,—On June 7th a meeting of the Bournemouth Division of the British Medical Association was held to discuss certain matters arising out of the Annual Report of Council. The most important subject discussed was the protection of medical practitioners discharging duties in pursuance of the Lunacy Acts. Two resolutions appealing to this question were proposed and carried, with only one dissentient. In the Supplement for June 16th (p. 253) you publish these two resolutions sent up from the Bournemouth Division, which read as follows:

I.—In regard to Section 330 of the Lunacy Act, 1890—(a) the onus of proof of want of reasonable care and want of good faith should be on the plaintiff (b) unless the plaintiff can satisfy the judge that he is able to prove in a court of law the want of reasonable care and good faith, the case should not proceed to trial, and (c) the judge should be able to call in expert opinion on the point of reasonable care in respect of medical certificates if he himself is in any doubt.

II.—If under Sections 13 and 16 of the Lunacy Act, 1890, a magistrate make an order to one or two medical men as the case may be (two medical men under Section 13 and one under Section 16) to examine a person believed to be of unsound mind it should be considered that the magistrate should be solely responsible as an instrument of the law and the doctors should have the status of a witness and enjoy the immunities of a witness.

I was present at that meeting and whole-heartedly supported both these resolutions. At the request of some of our members and with the consent of our chairman (Dr Asten), and at the suggestion of Dr Hawthorne, Chairman of the Representative Body of the Association, may I be allowed to state my reasons, emanating from many years' experience of the working of the Lunacy Acts, for supporting the above-named resolutions?

I should first like to draw the attention of your readers to the following recognized facts. All Lunacy Acts and Royal Commissions in Lunacy have been initiated and carried into being (1) for the protection of the persons alleged to be of unsound mind, for their supervision and care and treatment, (2) for the protection of the general public. Many sections of the Lunacy Act of 1890 deal with misdemeanours, and in Section 317, Clause 2, we find

Any person who makes a wilful misstatement of any material fact in any medical or other certificate or in any statement or report of bodily or mental condition under this Act shall be guilty of a misdemeanour.

But protection is given to the medical certifier under Section 330, Clauses 1 and 2

1 If any proceedings are taken against any person for signing a certificate under this Act such person shall not be liable to any civil or criminal proceedings whether on the ground of jurisdiction or on any other ground if such person has acted in good faith and with reasonable care.

2 If any proceedings are taken against any person for signing a certificate such proceedings upon summary application to the High Court or a Judge, may be stayed upon such terms as to costs and otherwise as the Court or Judge may think fit—if the Court or Judge is satisfied that there is no reasonable ground for alleging want of good faith or reasonable care.

It is, of course, only right and just to the person alleged to be of unsound mind that the greatest possible care should be taken by medical men before signing such certificates, for it must never be forgotten that such certificates mean practically that for a time, or perhaps for the rest of his life, the alleged person of unsound mind is deprived of all his civil rights, may lose appointments of much value, or have a lucrative partnership dissolved.

Prior to the 1890 Lunacy Act anyone could sign an order for the legal care, control, and treatment of a person of unsound mind as a result of actions and agitutions on the part of the public, the intervention of the magistrate became embodied in the Lunacy Act, and I am certain this intervention will never be done away with. But to avoid anxiety and expense to doctors against whom actions might be started, often by unscrupulous persons, and advised by equally unscrupulous and shady solicitors, Clauses 1 and 2 of Section 303 were inserted in the Act of 1890.

There is no doubt that the Parliamentary Committees of the British Medical Association and the Medico-Psychological Association, set up in 1889 (on both of which I had a seat), quite imagined when this Section 330 was discussed, and especially Clause 2, that the onus of proof before the judge of want of good faith and reasonable care would be on the plaintiff, for does not English law demand that the prosecution must establish the guilt of the accused rather than that the accused should have to prove his innocence? I do not think any single member of the British Medical Association will vote against Resolution I, and it need not be further discussed.

With regard to Resolution II it is clear that the British Medical Association's Committee in its evidence and suggestions before the Royal Commission agreed as to the principles embodied in this resolution, but the Royal Commission would not or could not see eye to eye with it. Surely the non-agreement of the Commission is no reason why the British Medical Association should not strive for these principles, not merely for the safety of the medical man, but for the safeguarding of the patient and the general public. Later on I shall hope to show how these principles are agreed to by eminent judges of the King's Bench, the Court of Appeal, and the House of Lords.

Let me state three classes of mental cases giving no end of anxiety to relations and being in certain degrees a danger and a nuisance to the public and yet cases refusing to place themselves as voluntary boarders under the Act for care and treatment. Yet in many of these cases the relatives dread taking the initiative, and the doctors fear certifying because they both know that the illness under proper control and care may be quickly recovered from, while they recognize that on discharge many patients will resent their loss of liberty, and if litigiously inclined and ill advised may cause no end of trouble and anxiety and expense to those who had taken what they believed to be the right and only course. I mention three special forms of mental disease in which this difficulty is most likely to arise.

(1) Cases of circular insanity in which periods of excitement and exaltation alternate with periods of deep depression while, either intervening or following after the latter, come periods of apparent normality.

(2) Cases of alcoholic insanity (not delirium) in which under legal care control and treatment the symptoms quickly clear up. In these cases the patient almost invariably feels great resentment on his discharge against those who have only acted for his welfare.

(3) Some cases of paranoia especially those so graphically described by Dr. Rutherford Jeffrey, medical superintendent of Bootham Park Mental Hospital, York, in his book *Common Symptoms of an Unsound Mind* and called by him false paranoia in which there are periods of apparent normality when the delusions of persecution are either in abeyance or non-assertive as to conduct. There are many such patients and they prove a source of great anxiety and trouble to the relatives to the family medical man and maybe to the public also. They are cases in which the medical man is afraid to certify on the initiative of a relative.

In all these cases such an alteration of the law as stated in Resolution II—giving medical men who sign certificates of lunacy by the direction and with the authority of a magistrate the status and immunity of an ordinary witness

—would really be a boon to many patients and a relief to relatives and the general public. This status and immunity should apply to all doctors signing certificates by the direction of a magistrate under Section 13 (private patients), Section 15 (persons of unsound mind found wandering) and Section 16 (rate-supported patients). In such cases information has to be given to a magistrate especially appointed under the Act of 1890 by the relieving officer or the police, and he thereupon directs and authorizes one, or two doctors, as the case may be, to examine and report to him, and he himself sees and examines the alleged person of unsound mind before making the order for his detention, care and treatment, whether in a public mental hospital, a registered mental hospital, a private mental hospital, or private care.

Now let me draw your readers' attention to the opinions of judges on this important matter.

The case of *Everett v. Griffiths* and another (the doctor) was first tried in the Court of King's Bench before the Lord Chief Justice. It was then taken to the Appeal Court and finally to the House of Lords and is reported in *Law Reports* (1921). It was the case of a rate-supported person about whom information had been given to the relieving officer. He had reported it to the magistrate Griffiths who had directed the Poor Law medical officer to examine and report. There is no doubt from the evidence that the doctor took great care and the patient was under his supervision prior to certification and detention in Colney Hatch, from which he quickly escaped. The action was tried before the Lord Chief Justice. The jury disagreed but the judge gave judgement for both defendants. For the magistrate because he was acting judicially in signing the order and for the doctor as the plaintiff's detention was caused not by the medical certificate but by the order of the magistrate. The doctor was consulted in an advisory capacity. In the Court of Appeal the appeal was dismissed and the Lord Chief Justice's judgement upheld. Lord Justice Atkin dissenting as he considered there was no difference between Section 16 and Section 6 which is the section dealing with the ordinary patient by a relative and two medical certificates and on these the magistrate is asked to sign an order. The case was taken to the House of Lords and by the Law Lords dismissed and the judgement of the Lord Chief Justice upheld. In giving judgement Lord Atkinson entirely disagreed with Lord Justice Atkin re Sections 13 and 16 being on the same footing as Section 6. The latter he said is a 'family affair' while the former are 'judicial'. Under Section 6 the magistrate need not see the patient while under Sections 13 and 16 he must.

Lord Moulton showed to my mind in all he said a distinct feeling that in these cases the medical man was protected. Such with these legal opinions of such eminent judges the British Medical Association should take heart and try to get this immunity once and for all decided in cases dealt with under these sections. Such alteration will, I believe, be from my long experience a blessing, not only to the patient, but to the relatives, their friends, and the general public, while the safeguarding of the alleged person of unsound mind will be well insured.

I hope I have made clear to all my reasons for supporting these resolutions, and I only wish I could have been able to attend the Cardiff Meeting, but this, unfortunately, I find impossible.

When the Voluntary Boarder Section is made to apply to public mental hospitals and private care much less certifying need be done, and when a proper and workable Early Treatment Bill is passed there will, I hope, be far less chances of vexatious actions against medical men for trying to the best of their ability to do what is right for their patients afflicted with mental disorders—I am, etc.,

Bournemouth June 27th

LIONEL A. WEATHERLY, M.D.

VOLUNTARY HOSPITALS AND THE STATE

SIR,—The proposals for "reform in local government" to be submitted to Parliament in the autumn session by the Minister of Health have now been published (*White Paper, Cmd 3134*). These proposals, as they affect the medical services, are separately described for London and for the provinces. In the provinces each county and county borough will be a complete unit of administration of all the medical services hitherto assigned to Poor Law authorities. In London the London County Council will become responsible for all Poor Law medical services, as well as those now performed by the Metropolitan Asylums Board,

which will cease to exist. The effect upon the voluntary hospitals will be indirect, but none the less real. All the hospitals other than the voluntary hospitals will be under a unified control by a body which will have the power of imposing a rate for their development and maintenance. Contrasted with these arrangements will be the position of the voluntary hospital, an isolated unit in each area, having to face the competition of a county organization with complete command of the rates. As the larger subscribers to hospitals are also ratepayers, the position must come about that the subscriber, faced with the necessity of paying an enormously increased rate for the public hospitals, will not be able, however desirous he may be, to make the same subscription to the voluntary hospitals that he may have done in the past. Centralization, backed by the power of the purse, is thus opposed to isolated private effort, and the ultimate effect upon the voluntary hospitals must, I think, be extremely serious.

It is, I submit, unfortunate that the voluntary system should be further menaced by recommendations in the Report of the Council of the British Medical Association to be brought forward for adoption by the Representative Body at Cardiff. In this Report it is suggested that "the first step in the attempt to co-ordinate the work of the voluntary and municipal hospitals must be the establishment of a central advisory authority appointed by the Minister of Health" (the italics are mine). I submit that if the Minister of Health is to have the chief voice in the appointment of that central advisory authority the voluntary system vanishes. The scheme is, as the Report itself mentions, on the same lines as the plan suggested by the Dawson Committee, whose recommendations were published in 1920. An editorial in the *Times* of December 2nd, 1927, commenting upon the Dawson plan, said

'The weakness of the scheme lies in the fact that the predominant partner is the health authority and that behind the health authority stands the Ministry of Health—that is the State. He would be a sanguine observer of existing methods who supposed that the voluntary spirit would remain undiminished in such close contact with what would of necessity soon become a highly organized service.' The lamb of voluntarism and the lion of socialism cannot lie down together.

My own opinion entirely coincides with that expressed by this leader in the *Times*. I am so much impressed with the danger to the voluntary system thus imminent that I put down an amendment to the Annual Report for consideration by the Marylebone Division at its meeting on June 28th, 1928, in the terms detailed below. The Marylebone Division probably includes more consultants than any other single Division of the British Medical Association. The secretary informed the meeting that fifteen hundred invitations to attend it had been sent out. Actually the meeting consisted of eleven persons, only four of whom were members of the teaching staffs of London hospitals. My amendment was rejected on a vote by this small meeting, seven voting against, three for, the chairman not voting. I cannot think that the staffs of voluntary hospitals are as indifferent on the matter as this singularly small attendance would indicate. I have given notice that I shall move an amendment to the Report of the Council when it comes before the Representative Body at Cardiff, my amendment being in the following words:

That the Representative Body having considered the scheme for the co-ordination of hospital provision submitted by the Council (Appendix 7 Annual Report) disapproves of the recommendation that the central advisory authority to co-ordinate the work of the voluntary and municipal hospitals be appointed by the Minister of Health inasmuch as such appointment would inevitably transfer the control of the voluntary hospitals to the State as represented by the Ministry of Health. The Representative Body desires to keep the voluntary system intact and would prefer to see a central advisory authority in which representatives of the voluntary hospitals would be in a majority and the co-ordination would be effected with a voluntary hospital acting as the primary or central hospital of any group of medical services to be thus co-ordinated.

I hope that I may have more support for this motion at Cardiff from the staffs of voluntary hospitals than was forthcoming at this very unrepresentative meeting of the Marylebone Division last week—I am, etc.,

London W 1 July 2nd.

E GRAHAM LITTLE

GASTRIC AND DUODENAL OPERATIONS

SIR,—I was wrong in believing that Sir Berkeley Moyulhan had any leanings towards the views of those who advocate gastrectomy as a treatment for duodenal ulcer, and I hasten to offer him my apologies.

His weighty opinion so definitely expressed in his courteous letter will, I hope, dissuade anyone in this country or America from adopting such a line of treatment—I am, etc.,

Liverpool June 30th.

F STRONG HEANEY

TREATMENT OF MALIGNANT DISEASE BY COLLOIDAL LEAD

SIR,—I have been informed that there is the possibility that my remarks (*Journal*, June 23rd, p. 1088) regarding the work of Dr Todd at Bristol with lead selenide may be misinterpreted to mean that the preparation used there was made "on my instructions." It seems impossible that such a construction can be put on my words, but if anyone should so misconstrue them I hasten to say that the work at Bristol, although based on our work in Liverpool, has been conducted entirely independently, and that the Bristol workers alone are responsible for what has been done. I congratulate them on their enterprise and success. Perhaps Dr Todd will allow me to point out that in his published report, by some oversight, the word "decidua" is used instead of "chorionic epithelium"—the two tissues are, of course, entirely different—the one is maternal, the other foetal.

Without in any way wishing to underrate the assistance given to us by Mr Patterson some years ago, which I have acknowledged in my earlier publications, I must point out that his claims (*Journal*, June 30th, p. 1134) are somewhat ridiculous. I first met Mr Patterson when he was a chemist, under Mr Ward, in the employ of the British Colloidal Company. I hoped that this company would be able to make for me colloidal preparations of lead. I had a long conversation with Mr Patterson and suggested various preparations of lead he should attempt to make, one of which was lead iodide—I have a letter from Mr Patterson, dated May 9th, 1920, which entirely confirms this statement. As a satisfactory preparation was not then produced, the company generously allowed Mr Patterson to come to Liverpool to work under my direction, and subsequent improvements made were suggested by me—I need not go into details, for we do not use the material now. Mr Patterson was never appointed to "take sole charge of the chemical work of [our] cancer research," nor did he ever do so, he may have been for a short time the only whole-time chemist working for us. It is, therefore, absurd of Mr Patterson to talk about "his" preparation. I regret to have to inflict such trumpery details on your readers—I am, etc.,

Liverpool, July 2nd.

W BLAIR BELL

* * We have received a copy of the interim report by Dr A T Todd and his colleagues at Bristol, entitled *Chemo-therapeutic Researches on Cancer, with Especial Reference to the Lead and Sulphur Groups*, to which reference was made by him in the letter printed in our issue of June 16th (p. 1048). This report is published by Messrs J W Arrowsmith, Ltd, of Bristol and London, at the price of 2s 6d—Ed B V J

BATTERSEA (ANTIVIVISECTION) HOSPITAL

SIR,—My attention has been drawn to a statement made by Mr J F Peart, F R C S, and published in your issue of June 23rd (p. 1080), giving an account of a meeting of the Research Defence Society from which it would appear that some people draw the wholly inaccurate conclusion that I was anxious to associate myself with methods in contravention of the accepted principles of the Battersea General (Antivivisection) Hospital. As chairman there for twelve years I think this calls for some explanation. Mr Peart was quite correct in stating that I was willing to afford him every facility for treatment other than was permitted at our hospital, provided it was not done

their During my term of office I always made it quite clear that patients and their relations should be at liberty to have any treatment they desired, and the patients should, if they wished, be removed to other hospitals if we were not able to give it. I consider it no part of the chairman's duty to act as adviser to medical experts or to lay down the law as to how a patient should be treated, except in so far as the principles of an antivenereal section hospital were concerned.

I held Mr. Peart in very great esteem, as I consider he did a great deal of valuable work for the Battersea Hospital, and although I could not take over his responsibilities, the rules and regulations of the hospital had to, as he has stated, be most strictly adhered to—I am, etc.,

London S.W. 7 July 1st

TENTERDEN

Sir—It has been brought to my notice that my remarks at the Research Defence Society meeting have been misconstructed as regards my reference to Lord Tenterden. In fairness to him I wish to state that I merely meant to convey that he gave me every assistance possible within the limits of his obligations to the hospital. Nothing could be further from the truth than that he tried in any way to infringe those obligations—I am, etc.,

London W. July 2nd

J. F. PEART

Obituary

JOHN WILLIAM MACKENZIE, O.B.E., T.D., M.D.

Physician the Northern Infirmary Inverness

We regret to record that Dr. J. W. MACKENZIE, physician to the Northern Infirmary, Inverness, died recently at his residence there from septic pneumonia, after an illness of only a week's duration.

John William Mackenzie was born in 1876 and received his medical education at Edinburgh University, graduating M.B., Ch.B. in 1892, and proceeding M.D. (with commendation) in 1903. He commenced practice in his native town in 1906, after gaining special experience in diseases of the ear, throat, and nose in London and Cardiff, and soon built up a large and successful practice. At the beginning of the war he was in command of the Highland Mounted Brigade Field Ambulance, with which he served with distinction in Gallipoli and Egypt, being subsequently promoted to the rank of lieutenant-colonel, for his services during the war he was twice mentioned in dispatches and awarded the O.B.E. On his return to Inverness he not only gave of his best to his greatly increasing practice, but also played a large part in the public affairs of his profession and of the community in which he laboured. He was a member of the medical staff of the Northern Infirmary as physician and as specialist in diseases of the throat, ear, and nose, and took a keen interest in the scheme for reconstructing and endowing that institution in an up-to-date form to serve as a key hospital for the Northern Highlands.

A colleague writes: His medical brethren were immensely indebted to Dr. Mackenzie for the time and effort he expended as honorary secretary of the Inverness Division of the British Medical Association, and at the time of his death he held office as a vice-president of the North of Scotland Branch. He was a Fellow of the Royal Society of Medicine, and a member of the Scottish Laryngological and Otological Society. In many ways he gave an enthusiastic helping hand to the civic activities of the capital of the Highlands. He possessed a kindly, lovable character, which endeared him as both friend and professional adviser to his patients, and which won the affection of all with whom he came in contact. His death is a severe loss to his medical brethren and to the northern public. An eloquent testimony to the affection which he inspired in them was given by the large attendance at his funeral, representatives of all classes and of many public bodies being present. He was indeed greatly loved and is deeply mourned, and widespread sympathy is felt for his widow.

Dr. ALEXANDER STEWART GORDON, who died suddenly at his residence in Inverkeithing on June 28th, was a native of Bathgate. He received his medical education at Edinburgh, where he graduated M.B., Ch.B. in 1904, and proceeded M.D. in 1910. In the latter year he also obtained the diploma in public health of the Royal Colleges of Physicians and Surgeons, Edinburgh. While still a student, he had acted as a member of the staff of the Edinburgh and East of Scotland Hospital which was dispatched to South Africa during the Boer war. After holding the post of house surgeon in Edinburgh Royal Infirmary to Sir Montagu Cottenill Dr. Gordon acquired the practice of the late Dr. Philip at Inverkeithing in 1911, and was appointed medical officer of health for the burgh. He was also parochial medical officer and local medical officer to the post office and school board. With the growth of the district around Inverkeithing consequent upon the construction of the naval base at Rosyth, Dr. Gordon's practice increased greatly and he was appointed Admiralty surgeon and agent. During the late war he was medical officer in charge of the troops of the inner Fort defences, and later medical officer to the R.A.I. station at Donibristle. His services during the war were recognized by the award of the Order of the British Empire. Dr. Gordon was a member of the British Medical Association and of various medical societies, he was the author of a paper on the "Refractory phase of the heart under digitalis and strophanthus." A well-known and popular practitioner throughout the district of West Fife, he was known to a wider circle as a skilled curler. Dr. Gordon had not reached the age of 50, and is survived by a widow and two children.

Dr. AMERIC LEWIS FLAXMAN, who died on June 11th at his residence, St. Nicholas, Pittenweem, had been in ill health for a long time, and virtually retired from practice some eight years ago. After obtaining the M.A. degree at Oxford in early life he later decided to take up medicine, and studied at Middlesex Hospital, becoming a Licentiate of the Society of Apothecaries of London in 1882. He subsequently held the appointments of clinical assistant to this hospital and resident clinical assistant in the East London Hospital for Children. He settled thereafter in Pittenweem and St. Monance, where he conducted a large practice for some forty years. In middle-life he was well known in sporting circles as a lover of horses and dogs. For a number of years he took part successfully in trotting matches at a time when this form of racing was popular in Britain. He was a well-known breeder of dogs, and among dog fanciers is still known as the introducer of the breed of white West Highland terriers, which has recently become fashionable. He was also fond of travel, and despite the calls of a large circle of patients by whom he was greatly beloved, he had managed to pay several visits to the West Indies and to the East. He was a descendant of John Flaxman, the celebrated sculptor and ceramic artist of the eighteenth century, of whom he preserved numerous mementoes.

Dr. BENJAMIN POPE BANTLETT, who died in his sleep, on June 20th, at his residence at Bourton, Dorset, was born in 1861, and received his medical education at Guy's Hospital, he obtained the diploma L.S.A. in 1882 and the M.R.C.S. in 1883. After holding a resident appointment at Leicester Infirmary, he assisted the late Dr. Webber of Crewkerne, Somerset, for two years, and then settled in Bourton in 1886, where he practised for forty-two years. He was district medical officer under the More and Shaftesbury boards of guardians, and medical officer of health of the Mere Rural District for the whole of that time. Throughout the war he was anaesthetist and radio-grapher of the Red Cross Hospitals at More, Wilts, and Plank House, Gillingham, Dorset. He held the post of chairman of the Bourton parish council from its inception, and was an ardent Freemason, being a past master of the Dorset Masters Lodge and a past officer of the Provincial Grand Lodge of Dorset. He had a great reputation as a geologist, and was an expert on the Bourton neigh-

bomhood, his collection of fossils and specimens being very complete. His health had been failing for the past two years, but he continued in his practice until last April. He is survived by one son and six daughters. He had been a member of the British Medical Association for forty-five years, having served for various periods on the Somersetshire, Dorset, and Wiltshire Panel Committees. He was a member of the Inoculture Committee of the West Dorset Division from 1917 to 1921, and of the Dorset and West Hants Branch Council from 1919 to 1921.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Foot-and-Mouth Disease: Inspection of Imported Meat

On June 27th Lord STRACHAN, in the House of Lords, raised the question of the introduction of foot and mouth disease into this country. He moved that it was undesirable that the Ministry of Agriculture should accept foreign inspection of imported meat from South American countries where foot and mouth disease prevailed while refusing to accept foreign inspection of meat from Continental countries. He urged the Government to stop the danger of infection from chilled meat which he said was practically taking the place of frozen meat. Lord STRACHAN in reply said that there were very good reasons why the Government should discriminate between meat imported from the Continent and that from South America. It had been clearly proved that infection was introduced into this country by the carcasses of pigs brought from the Continent. There had been no proof, however, that infection had been introduced in carcasses from South America. There had been a good many surmises and the Ministry of Agriculture had taken every possible step to prevent infection being brought in. Although there might be possibilities of the survival of the virus in the carcasses from South America, time was so important a factor that it could not be ignored and in practice it was wise to assume that the longer a carcass took to reach this country the less likelihood there was of the virus surviving in or on it. The experiments by the Research Department had not yet developed in the war the Ministry would desire in that the experimenters had not yet found a direct antidote to the disease. The experiments were in a more or less tentative condition and so far the results were not conclusive. It was impossible to say definitely how long the virus continued alive in the blood or bones of carcasses. There was no evidence to show that freezing the meat would kill the virus which seemed to live in the bones just as long as in frozen meat. To deal with this an order had been issued with regard to the disposal of bones.

Lord BLENDISZ who has just returned from South America said that the Argentine Government were doing their utmost to carry out effective inspection. It might be the opinion of some medical authorities here that frozen meat was just as wholesome and nutritious as chilled meat. It was quite certain, however, that that was not the view of a large number of medical authorities in this country. The British public quite properly has developed a taste for chilled meat compared with frozen meat as being more attractive to the palate and in their opinion more wholesome and nutritious. There was no scientific information to lead them to believe that the danger of infection would be lessened by the importation of frozen carcasses in preference to chilled. Lord EASELY said that frozen meat contained an advantage over chilled meat. The Ministry of Agriculture ought to alter the regulations about the disposal of bones and penalize the butchers if they allowed an unboiled bone to leave their premises. A quarantine ought to be placed on chilled meat. Lord STRACHAN withdrew his motion.

Scientific Cinematograph Films Suggested Exemption from Duty

During the Committee stage of the Finance Bill in the House of Commons on July 3rd Captain FRASER moved a new clause to exempt from duty films recording scientific investigations or research imported into Great Britain or Northern Ireland if the Commissioners were satisfied that the films would not be sold, hired, or publicly exhibited for profit. He said that the man who had carried out researches with a microscope or in other directions of a scientific and particularly of a medical scientific, kind now found it possible through the technique which had been developed to record those researches and investigations on a film. Science knew no barriers and ought not to be subject to any taxation. There had recently been one or two instances where eminent foreign scientists desired to bring to this country films recording valuable work they had done not for profit but to demonstrate to their colleagues working on similar lines in this country. Cancer was very likely to be alleviated by some of the researches being made in America, England and Germany by men who used the microscope and the cinematograph for recording their researches. The free interchange of the results of their investigations was something which no taxation should be allowed to impede.

Dr. STURGES seconded the new clause. He said that its object was one with which every member must have sympathy. Even in the few years since 1925 the importance of these scientific films had considerably increased. Many of them had originated in America, Germany and other countries and were most valuable for teaching and scientific purposes. It had always been one of the

proudest features of science that it recognised no frontiers. There ought to be free trade in all that appertained to science and research and anything that would make for the alleviation of human suffering. Therefore there could be no question that the suggested removal of this taxation would have the sympathy of them all and no doubt also of the Chancellor of the Exchequer. The only possible objection was that of administration but it should be possible for the scientific bodies to which such films would be assigned to give a certificate which would permit of the working of this exemption without causing much administrative difficulty. He hoped that the Chancellor of the Exchequer would receive the proposal in a sympathetic spirit. If he did he would receive the thanks not only of scientific bodies, but of general public opinion in this country.

Mr. A. M. SAMUEL said that this clause had received the most careful consideration with a desire if possible to give effect to it. It had been found, however, that to distinguish the scientific films from those which could be shown in the ordinary way would be impossible from an administrative point of view. The revenue authorities could not trace films which were produced as scientific films in these days of popular science and be sure that they were not subsequently shown in picture houses in the ordinary way.

Captain FRASER appealed to the Chancellor of the Exchequer to give the matter careful reconsideration as the films to which the clause referred were only of scientific interest and were in no sense of the word 'popular'.

Mr. CHURCHILL replied that he could give no undertaking in the matter. In view of what Captain Fraser had said, however, he would see that all the facts which had been adduced were examined once again. Those responsible for making that inquiry would receive any further evidence that Captain Fraser might bring forward.

The proposed clause was then withdrawn.

Dogs Act (Amendment) Bill

The Dogs Act (Amendment) Bill was read the second time in the House of Lords on June 28th. Lord BEATIE pointed out that under the principal Act no dog seized by the police could be given or sold for the purposes of vivisection but under this bill dogs which were found were not so protected. He intimated that in the Committee stage he would move an amendment to deal with this point.

Shops Bill

The Shops (Hours of Closing) Bill was read a third time by the House of Commons on June 29th. During the discussion on the Report stage that day Dr. DAVIDSON SHIELDS said chocolates and ice-cream were better for health if not taken late at night. It was in the interests of the community that as few chocolates and as little ice-cream as possible should be taken after 8 o'clock at night. On the motion of Sir VIVIAN HENDERSON an amendment was made adding to the proviso about the sale of refreshments after closing hours the words including table waters, sweets, chocolates, sugar confectionery and ice-cream.

Medical Services in the Highlands and Islands.—Sir J. GILMOUR, replying on July 3rd to Sir A. Sinclair, said the statement in the Report of the Scottish Board of Health that the gap was widening between the standard of medical services in the Highlands and that in the Lowlands expressed the view of the Consultative Council on Highlands and Islands whose report he had seen and was now considering. The money available in the Highlands and Islands (Medical Service) Fund was sufficient to maintain the medical services on their present scale during the current year. It was anticipated, however, that the fund would be exhausted by the middle of the next financial year before which time the question of what further financial provision should be made would be fully considered in the light of the whole circumstances of the case. Sir A. SINCLAIR asked if provision would be made in the meantime for catering up the leeway as well as maintaining these services at the lower level to which they had fallen. Sir J. GILMOUR said that the provision for this year had been made out and would be carried out to the full.

Post-operation Tetanus.—On July 3rd Sir J. GILMOUR in reply to a question said that consideration of the report on post-operation tetanus was still proceeding but he was not yet in a position to make a statement. He hoped to be able to do so very shortly.

Annual Returns of Vaccination Officers.—On July 3rd Mr. CHAMBERLAIN told Mr. Pethick Lawrence that a summary of the annual returns of the vaccination officers for the years 1918 to 1925 would be found in Appendix A to the report of the Chief Medical Officer of the Ministry for 1926, and similar figures for 1926 would be published in the forthcoming report for 1927. The preparation of a return for each county would involve an expenditure of time and labour out of proportion to the value of such a return.

Small-pox Inspection of Casuals.—On June 28th Mr. CHAMBERLAIN in an answer to Mr. Shepherd said the present order for the medical inspection of casuals was due to expire at the end of June but he was continuing it to the end of September. In the week ended June 23rd there were 230 cases of small-pox notified in England and Wales. From January 24th to June 25th 1923 the number of cases of small-pox reported among casuals was 124. Mr. SHEPHERD asked if many of these cases would not be prevented if the casuals were medically inspected on arrival, instead of when they had been in the casual ward over twelve hours. Mr. CHAMBERLAIN said it might be impossible to examine all casuals at the moment of arrival, but he would look into the matter.

Medical News.

THE Fellowship of Medicine announces that Dr A O Roxburgh will give a dermatological demonstration on July 10th, at 2.30 p.m., in the outpatient department of St John's Hospital, at 262, Uxbridge Road, W 12. On July 11th there will be a urology demonstration at 2.30 p.m. at All Saints Hospital, and on July 12th, at 3 p.m., Mr A special course in ophthalmology demonstration at the Royal Westminster Ophthalmic Hospital. These demonstrations are free to medical practitioners. A course of official demonstrations, operations, and lectures on medicine, surgery, and the specialties will be held at the Prince of Wales's Hospital, Tottenham from July 9th to 21st, from 10.30 to 5.30 daily. A special course in ophthalmology at St Mark's Hospital, from July 9th to 14th, will consist of lectures, demonstrations, and operations. A whole day course at Queen Mary's Hospital from August 27th to September 8th, will include demonstrations in medicine, surgery, and the specialties. There will be a course in diseases of the chest at the Brompton Hospital from July 30th to August 4th, one in diseases of infants at the Infants Hospital, Westminster, from August 13th to 25th, and another in urology at All Saints Hospital, from August 7th to September 1st. Copies of all syllabuses and information on other post graduate work may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W 1.

DR E A COCKayne, physician to the Middlesex Hospital, has joined the Medical Advisory Committee of the Asthma Research Council, and Dr T E Fremantle M.F. has joined the Council. Active steps are now being taken to prosecute the investigation of the causes and possible cures of asthma and its kindred complaints. An advertisement will be found elsewhere in this issue for a part-time research scholar to investigate inhalation and physical treatment. The selected candidate will be required to visit Mount Doro and other Continental resorts for the treatment of asthma prior to taking up his appointment in London.

THE June issue of *The World's Health* appears as a special number published jointly by the League of Red Cross Societies and the International Union against Venereal Diseases. It contains articles by Professor A Bayot, chairman of the Union, Dr Cavallion, chief of the department of venereal disease control in the French Ministry of Health, and Dr 1. Lambert, chief of the health division, League of Red Cross Societies. Reports are given of the measures adopted and the progress made in different countries, and there are accounts of the work in this respect carried out by the League of Nations and the International Labour Office. The review may be obtained from the League of Red Cross Societies, 2 Avenue Velasquez, Paris VIII^e, price 1s.

THE large number of guides to London's complex transport system indicate that few have been found entirely satisfactory, some have been too complicated for ordinary use and others have been too bulky. *The Tube Bus Guide to London*, however, escapes these faults and it should prove exceedingly useful to visitors and Londoners alike. It gives in unambiguous terms the most convenient methods of travel between all the principal landmarks and in an area where the streets are counted in hundreds. This is as much guidance as one is entitled to expect. The information regarding such matters as omnibus stopping places appears to be more precise than usual, while the chief centres are illustrated by unusually clear little maps. In size the booklet is no larger than the third part of a pack of ordinary playing cards. It has been prepared by Mr J C Willis, M.A., So D, F.R.S., and is published at the price of 6d by Messrs W Heffer and Sons, Cambridge.

MR. C E KENNETH MEES, D.Sc., will give a public lecture on "Physics in Photography," on Thursday, July 12th, at 8 p.m. in the rooms of the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W C 2, under the chairmanship of Sir William Pope.

DR LEONHARD SEIF of Munich will give a lecture on individual psychology in general practice diagnosis, and treatment of the neuroses on Thursday, July 12th, at 8.30 p.m., in the rooms of the Adler Society, 55, Gower Street, W C 1. A discussion will follow the lecture, to which practitioners and senior students are invited.

THE Harben gold medal of the Royal Institute of Public Health was presented on June 28th to Sir Ronald Ross in recognition of his great work in making the tropics healthier. The medal is awarded every three years for eminent services to public health, irrespective of nationality.

A NEW edition—the nineteenth—of volume I of Martindale and Westcott's *Extra Pharmacopoeia* revised and brought up to date by W Harrison Martindale, Ph.D., is published this week by H K Lewis and Co., Ltd.

THE current number of the *Police Journal*, a quarterly review for the police forces of the Empire, the first issue of which was reviewed on January 14th (p. 67) contains several articles of some medical legal interest. One of these Professor Sydney Smith's paper on "The identification of fire arms and projectiles, as illustrated by the case of the murder of Sir Loo Stack Pasha," has been reprinted, by permission, from our issue of January 2nd, 1926. Dr M Hamblin Smith, medical officer to H M Prison, Birmingham, contributes an interesting article on "The value of psychology in court work" which should be of considerable use to those to whom it is primarily addressed. "The prosecution of offenders English practice," by Sir Archibald Bodkin, Director of Public Prosecutions, gives a clear explanation of a legal process which is frequently misunderstood, but whose deservous inclusion in the average person's stock of "general knowledge."

A PUBLICATION of some fifty pages entitled *Actino therapy or Ultra violet Radiation*, and illustrating the apparatus of the Cox Cavendish Electrical Company, Limited (105, Great Portland Street, W), contains particulars of a bewildering variety of mercury vapour and tungsten and carbon arc lamps, in one apparatus these three types are combined on the one stand, so that any one or more of them can be used by a simple adjustment. Attention is drawn to the quartz mercury arc lamp, supplied in various forms under the name of "ultraro." In a quartz mercury vapour lamp termed the "nivistar" the old type of water cooled vacuum has been replaced by a forced draught. The latest developments in ultra violet lamp production seem to relate not so much to the source of the radiation as to its adjustment to suit various positions and needs.

THE following appointments have recently been made in foreign medical centres: Dr Alfred Gutlich of Greifswald, professor of otolaryngology at Cologne. Dr S Weber of Kiev, professor of otolaryngology at Riga and Dr Akira Agata, professor of hormone chemistry at Tokyo.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the Journal should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563, and 9564* (internal exchange four lines).

QUERIES AND ANSWERS

INJECTION TREATMENT OF VARICOSE VEINS
"G W J" would like to know whether there are any hospitals in Central London where varicose veins are treated by injection.

FINGER SUCKING
"S C M" asks for suggestions for the cure of finger sucking in an infant aged 20 weeks. The habit started when she was 4 weeks old. Local application of aloes and tincture of asafoetida has been tried without success.

FORMICATION
DR JOHN THOMPSON (Lisburn) asks for suggestions in the treatment of formication of the skin. The patient's sensations commence in the back and pass into and over the head. At times they start in the epigastric region.

STATUS EPILEPTICUS

DR L. HARRIS LISTON (Middleton St George oo Durham) writes in answer to "I O B's" query about the treatment of status epilepticus I may advise as I have treated many such and not seen a death since I adopted the outling short method of giving a hypodermic injection of 1/100 grain hyosceline hydrobromide. One then is usually sufficient, occasionally another after an hour's interval if the convulsions have not ceased and rarely a third is needed. A useful combination is hyosceline hydrobromide 1/100 grain morphine sulphate 1/6 grain, and atropine sulphate 1/180 grain, and this can be obtained as tabloid hypodermic "A" (Burroughs Wellcome and Co.) I would also advise the administration of luminal sodium 1 grain every night and a dose of saline every morning.

TREATMENT OF SITTIC TONSILS

"J A E" writes In the letter on tonsil suction printed in the *Journal* of June 16th (p 1048), Dr R Scott Stevenson quotes a formula of Sir James Dundas Grant iodine gr 1, acetic other (acid free) 3ij glycerol ad 3j I prescribed this only two days ago but the prescription was returned by the chemist on the ground that the acetic other was "incompatible" with the glycerol He states that his acetic other was definitely acid free I did not know enough to argue the matter and I substituted Mandl's patent I should like very much to use the Dundas Grant formula, and I should be grateful if you can suggest anything which will help.

* * * We have referred this inquiry to Sir James Dundas Grant, who replies

As the ingredients of the iodine acetic ether and glycerol paint for the tonsils, formulated by me, are not strictly miscible, it is advisable to dispense a fluid ounce of the mixture in a two-ounce bottle, so as to allow of shaking up before application.

INCOME TAX

Cash Basis

"E M A W" states that for some years he has paid income tax on the basis of fees earned and inquires whether there is any definite ruling on the question.

* * * It has to be admitted that the legal basis is the value of fees earned—that is, the amount of gross bookings for the year less a carefully ascertained allowance for probable losses by non-payment. But for many years the revenue authorities have agreed as a concession for mutual convenience to accept, in lieu of the strict gross amount, the total of the cash receipts provided that there are no circumstances such as the growth of the practice which render that basis an unfair index of the true earnings. The matter was discussed some years ago between a prominent official at Somerset House and a deputation representing the profession and the above is the gist of the agreed position.

Proof of Partnership

"H I J" has recently taken a into partnership and has been requested by the inspector of taxes to forward the partnership agreement for perusal.

* * * So far as our knowledge goes such a request is not usual in the case of a professional partnership, where the bona fides of the parties is undoubted and the facts are free from the complications that may attend similar agreements in the business world. We think therefore that our correspondent is justified in demurring to the request, while supplying such information with regard to the terms of the agreement as may be relevant.

LETTERS, NOTES, ETC.

HERPES AND VARICELLA.

DR VAUGHAN PENDREN (East Shooon) writes. My brother-in-law had a severe attack of herpes, and both his daughters developed varicella two weeks later. A boy aged 12 contracted a mild attack of herpes and a fortnight later his sister and two brothers younger than he were all down with chicken pox. These make my sixth experience of this phenomenon.

HOSPITALS FOR MIDDLE CLASS PATIENTS

THE RIGHT REV MONSIEUR CARTON DE WIART writes. Speaking at the conference of the British Hospitals Association at Southport Sir Thomas Harder is reported to have said that one of the most urgent of our problems to-day was the provision of adequate medical and surgical treatment for middle-class patients. "It is a crying need," he said. "We in London have no alternative between the general wards of the large hospital and the private nursing home, where, often enough, the cost to the patient is absolutely prohibitive." May I be allowed to state that a hospital for the middle-classes has been in existence since 1913 in the north of London. St Andrew's Hospital, Dollis Hill, for the professional and middle-classes was opened in 1913 for the reception of patients who while not suitable subjects for free treatment in charitable institutions are yet unable to meet the charges necessary to secure adequate medical or surgical treatment in private nursing homes. Standing on the crest of Dollis Hill it commands a beautiful view, in all directions, of the

picturesque country outlying London. The building has been equipped and furnished according to all modern requirements and stands in its own grounds of seventeen acres. Patients are admitted only on the recommendation of their own medical adviser. They are received irrespective of nationality or creed. Medical and surgical cases are received but those of a mental, contagious, consumptive, or venereal nature are not admitted. The hospital depends for its maintenance upon voluntary contributions and patients' payments. It is under the care of a most efficient honorary medical staff and two resident medical officers. It is now well known and its accommodation is taxed to the utmost. The number of beds must be increased at once. The opening of a children's ward is imperative, and more accommodation must be provided for the staff. The cost of the extension will be £33,000 towards which £6,601 is available. To all who are interested in this work and anxious to provide for this "crying need," we urgently appeal for assistance to enable us to provide the necessary accommodation. Plans have been prepared and building can proceed at once if help is forthcoming. I all particulars concerning the hospital will be supplied on application to the Administrator, St Andrew's Hospital, Dollis Hill, N.W.2.

MIDWIFERY MORTALITY

DR J. H. DUBOIS (Workington) writes. Dr Roxburgh in his letter (June 30th, p 1126) has pointed out the danger of hounding over midwives to "a body of midwives who are licensed to attend cases but who are totally unfit to take the responsibility thrown upon them." This is due to their very elementary and inefficient training, as at present any woman (many of an indifferent class) with no knowledge of surgical and medical nursing is, given one year's midwifery training and turned out licensed. I do not think this is good for the patients or doctors. No woman should be eligible for the examination in midwifery until she has had three years' thorough training in hospital and has passed the State examination in general nursing. The doctor spends at least five years in training, the trained nurse with her maternity spends four years, the untrained woman spends a year at midwifery and is then licensed. Another bad feature is that these untrained nurses but licensed midwives are sent out to country districts and are expected to attend cases of all kinds surgical or medical or midwifery, which is unfair to trained nurses and to those treated by them.

DR FREDERICK RUSSELL (Southend-on-Sea) writes. Will you allow me to plead for serious consideration of Dr Roxburgh's letter? For a long time I have been striving to draw attention to the fact that the majority of practitioners who are not attached to the ones affected but there are some who until affected peculiarly. What is most serious is the loss of professional skill and knowledge that must come to them. I write feebly because I have made it my business to watch the story of the profession for the last thirty-five years. When the general practitioners refused to man the clinics I knew they were making a fatal mistake. The idea of retaining an imagined surgical monopoly has driven the members of the Hospitals Association to uphold blindly a voluntary system which has been compelled to be more scrupulous as to how money was raised for the voluntary hospitals. This has been in vain, and the Hospital Savings Association and the middle-class hospitals will in the end hurt them financially as well as the general practitioners, as Dr Roxburgh so ably points out, these organizations will render the practitioners less efficient and more ignorant. Every surgical case will go straight to the hospitals. When I was a young practitioner in Lancashire all minor surgery and most of the patients with fractures and dislocations, were attended by general practitioners in their surgeries or in the workmen's homes. But when the employers were able to persuade the workmen to give weekly contributions to the hospitals then they stopped paying the general practitioners and all surgical cases were dealt with at the hospitals. The divorce of the general practitioners from the hospitals and the clinics will go on for a time, but finally medical men of all kinds must be paid for all the work they do for the nation and the general practitioners will have to be attached to the hospitals and clinics. The profession must awake to a realization of what is going on.

CORRECTION.

In the annotation entitled "Fine work and eyestrain" published in the *Journal* of June 30th (p 1119) the name of the ophthalmic surgeon referred to appeared as "Mr T. G. Clegg", this should have been Mr J. Gray Clegg.

In Mr R. Chalmers's note on pneumonia after operation for gastric and duodenal ulcers (June 30th p 1134) line 6 in column 2 should read "Morrison's and anaprapubic pouches." On the second day consolidation of the left lower lobe appeared.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 47, 48, 49, 52, 53, 54, and 55 of our advertisement columns and advertisements as to partnerships, residencies and locum tenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 11.

Remarks

ON

THE SURGICAL TREATMENT OF DIVERTICULITIS

BY

K. W. MONSARRAT, M.B., F.R.C.S.F.,

SURGEON TO THE NORTHERN HOSPITAL, LIVERPOOL, LECTURER IN OPERATIVE SURGERY, UNIVERSITY OF LIVERPOOL

The figures for the distribution of diverticula in the colon have been given by Dr Spriggs in 158 cases, as follows: pelvic colon 116, descending colon 76, ascending colon 30, transverse colon 31, whole colon 23, caecum 7. Of these 158 cases 12 per cent had an inflammatory process associated with the diverticula—in other words, diverticulitis.

From the point of view of the surgeon the following two questions are important: (1) In what proportion of cases is diverticulosis confined to the iliac and pelvic colon? (2) In diverticulitis is the condition restricted as a rule to one limited section of the bowel, or does it usually involve a considerable length of the colon simultaneously? I put these questions lately to Mr Marver of Ruthin Castle, and he has answered as follows:

In the last 100 consecutive cases of diverticulosis 16 had proceeded to diverticulitis at one or more points. In only 3 cases were the hypertrophic changes confined to the iliac and pelvic colon exclusively. In 11 of the 16 cases of diverticulitis the disease in the pelvic and iliac colon was associated with diverticulosis in other parts. In 8 of the cases less than 6 inches of bowel was hypertrophied; in the other 8 there was either more than 6 inches affected or more than one area.

These facts have a bearing on the operative treatment, more particularly on the question of resection, which I shall discuss later. In the cases of acute inflammatory colitis originating in diverticula a very long length of the bowel is usually infiltrated.

As a preliminary to the discussion of treatment it is necessary to distinguish the different clinical conditions which have their beginnings in diverticulitis, the acute and the chronic, and the sequelae or complications. These may be defined as follows:

1. Acute diverticulitis
2. Chronic diverticulitis
3. Acute perforative diverticulitis
4. Chronic perforative diverticulitis
5. Diverticulitis with stenosis

I have seen in all 18 cases suffering from the disease. My experience agrees with that of those who find it comparatively uncommon among the industrial classes—only six of my cases were seen in hospital.

The cases may be tabulated as follows:

Diverticulitis (18 Cases)

Type	Treatment	Result
Acute without complication—2 cases	1. None 2. Caecostomy	— D
Chronic without complication—2 cases	1. None 2. Fixation and wrapping	— C
Acute perforation general peritonitis—4 cases	1. Diverticulum excised and drainage 2. Diverticulum excised and drainage 3. Drainage 4. Drainage	C C C D
Chronic perforation with abscess—6 cases	1. Drainage 2. Drainage, separation of adhesions 3. Drainage 4. Drainage 5. Drainage 6. Drainage	C F C C C C
Stenosis—4 cases	1. No operation 2. Short circuit 3. Colostomy 4. Resection	— C C C

1. Acute Diverticulitis

This type is subacute at the start. The patient has some vague abdominal pain which increases in severity until, at the end of about forty-eight hours, he is acutely ill with severe localized pain, pyrexia, and increased

pulse rate. On examination a large extremely tender tumour is found usually in the left lower abdomen. The following case is typical:

A woman aged 61 was first seen on September 14th, 1925. For a week previously she had been ill with fever, occasional vomiting, constipation and acute abdominal pain. On examination a large tender tumour extended from the left iliac fossa as far up as the lower left ribs. The diagnosis was acute diverticulitis of the iliac and descending colon. I advised that no operation should be done unless there were definite signs of abscess. This inflammatory mass gradually disappeared. She had a slight recurrence of the condition in November 1926. Her doctor reports to me that in January 1927 he could make out nothing but a little thickening of the colon further that she had had no signs of stenosis and that by avoiding salts and by careful dieting she had remained well up to the present.

2. Chronic Diverticulitis

The chronic form of the disease is the commonest of all. The clinical features have been described in detail by Dr Spriggs, and I shall take the liberty of epitomizing his account. The patient has abdominal discomfort, less often pain, in the lower abdomen at or about the navel, but especially in the left iliac fossa. General flatulence and a feeling of distension are complained of. Constipation is frequent, or irregularity of the bowels or diarrhoea, or a sense of incomplete evacuation. Occasionally there is haemorrhage from the rectum. A sausage-shaped tumour, sometimes tender, but not always, can be felt in the left iliac fossa except in the obese. The following is an example of this chronic type:

A man aged 60 was first seen on March 23rd 1927. This patient had had attacks of abdominal pain at intervals for about two years. The pain had never been acute. His chief complaint was total loss of appetite. There had been considerable loss of flesh but this had not been progressive; he had been persistently troubled with flatulence. The site of the pain was in the left iliac fossa. Growth of the colon was suspected. Operation was performed on March 27th 1927. The pelvic colon was found adherent to the parietes in the left side of the pelvis. It was freed; the condition was considered to be inflammatory and due to diverticulitis. The adherent part of the colon was wrapped in omentum; a forty-eight hour drain was placed in the pelvis. For the last nine months he has been free from symptoms and his appetite has returned.

3. Acute Perforation

Acute perforation may be the initial symptom of the disease. This was so in all of the four cases of perforation on which I have operated, the duration of the symptoms before operation being six hours, thirty-six hours, four days, and one week. In one case the perforation concerned the transverse colon, in one the descending colon, in the remaining two the pelvic colon. The sequelae of this accident are those which would be expected to follow a perforation at this bowel site.

In one of my cases, the transverse colon perforation, there was an unlimited peritonitis, but the operation was done within six hours and recovery followed resection of the diverticulum, cleansing of the peritoneum, and drainage.

In the second case there was also an unlimited peritonitis.

The patient was admitted to hospital after thirty-six hours; his pulse rate was 132, his temperature 100.8° F, and the abdomen showed signs of an acute and generalized peritonitis of a severe type. A perforation of a diverticulum of the sigmoid colon was found and an intense diffuse peritonitis with fetid blood stained exudate. He died nine days after operation from persistence of the peritonitis and ileus.

In the third case the resultant infection was more localized.

The patient was a woman aged 44; the onset was sudden severe hypogastric pain with vomiting. On the fourth day there was an exacerbation of the pain with a pulse rate of 120 and temperature of 100.4° F. When seen she had signs of an acute peritoneal infection in the lower abdomen. A perforated diverticulum of the pelvic colon was demonstrated; the bowel having become adherent to the parietes in the pelvis there was a large pelvic collection of fetid pus. The diverticulum was excised; the pelvis drained and recovery followed.

In the fourth case the infection following the perforation was also localized.

This patient was also a woman aged 39. The symptoms were a week old when she was admitted to hospital. Her illness commenced with acute pain around the umbilicus and then in the left iliac fossa throughout the week she vomited frequently. At the end of the week she had a temperature of 101.4° F, and a pulse of 110 with signs of an acute infection in the lower abdomen towards the left side. A sloughed diverticulum of the descending colon was found and a large purulent collection in the left iliac fossa. After operation she had a faecal fistula which closed in three weeks.

The sequelae of this accident of perforation are similar to those following a perforative lesion of the appendix, the peritonitis is of a severe type and localization may or may not occur.

4 Chronic Perforation

There is no simply cut line between the cases of acute and the cases of chronic perforation. This group comprises those in which there is no sudden flooding of the peritoneum, where the perforation is shut off before it is complete and the typical sequel is an abscess. In fact, the group is best described as "chronic perforation with abscess," and may include the cases where no single gross perforation is demonstrated. If so, it will include all the cases of so-called "pericolicitis sinistra," the old original term. It will form the largest group which comes under surgical treatment.

Six of my cases belong to this group. One case was seen in an attack, of which the patient had had several in the previous two years. The disease was recent in the remaining five. They illustrate the variations which will arise in the clinical course according to the site of the focus and its limitation. Four of them were simple abscess evacuations in which the symptoms had been present nine weeks, fifteen days, fourteen days and four days. Healing after evacuation occurred in seventeen days, twenty-two days, twenty-eight days and twenty-eight days. In one case the ascending colon was the part of the bowel concerned, in the other three the sigmoid colon. The remaining two cases have points of special interest.

1 A female patient, aged 40, who had an attack of sharp pain in the lower abdomen six weeks previously. She had a second attack three weeks later and a third a week after this. In the last attack the pain was hypogastric, she vomited several times and the pain lasted three days. The pre-operative diagnosis was appendicitis. The appendix was healthy, a mass was found by the examining hand on the pelvic brim on the left side. The mass consisted of ileum adherent to iliac colon and on separation an abscess was opened. A perforation of a diverticulum was demonstrated on the mesenteric aspect of the iliac colon. The wound was drained and healing took place in three weeks.

The last case of the group illustrates an important surgical point to which I shall refer later.

2 A male patient, aged 43, for two years had had short attacks of abdominal pain of moderate severity. He came under observation in the course of an attack which had lasted a month—an exceptionally long time. He was ill with pyrexia and diarrhoea. Above the symphysis pubis and to the left of the middle line was an acutely tender mass. The diagnosis was diverticulitis with abscess. At operation an abscess was found buried in a linited mass of pelvic colon and adherent ileum. A faecal fistula followed this operation and has persisted up to the present rendering the patient unable to follow his occupation. Some months after operation the Wassermann test gave a double plus result and this may have had something to do with the persistence of the fistula.

5 Diverticulitis with Stenosis

Attacks of flatulent distension with actual colic are comparatively frequent incidents in many cases of chronic diverticulitis. Usually they are subacute and can be warded off by diet, a medical man of my acquaintance found complete relief from recurring attacks of this kind during a month spent in Barcelona eating the food of the country cooked in oil. By continuing the same type of cooking at home he has escaped further attacks during the last eighteen months or so.

There are four cases of persistent subacute obstruction from stenosis in my list.

1 A man, aged 61, in February 1926 had an attack of constipation with distension and gripping pain. Radiological examination demonstrated obstruction of the colon at the pelvic brim. The abdomen was opened by another surgeon, no growth was found but diverticulitis of the pelvic colon was demonstrated. Nothing further was done. I saw this patient in October 1927, he then complained of troublesome constipation and occasional distension. The pelvic colon was tender to palpation. A further radiological examination showed diverticulitis of the pelvic colon and many diverticula elsewhere. As he had no progressive symptoms no operation was advised.

2 The second case is that of a man, aged 47, who complained of constipation varied by occasional diarrhoea and also occasional haemorrhage of four months duration. The pelvic colon could be felt as an indurated and tender mass in the left iliac fossa and into the loin. Operation showed the whole length of the pelvic colon indurated with inflammatory exudate. On account of the signs of stenosis a transverse colostomy was performed. With irrigation the condition of the bowel improved so that it was possible to close the colostomy in two months, the stenosis being relieved.

3 The patient in this case was a woman, aged 42. During the previous eight years she had had six attacks of abdominal pain, diarrhoea and haemorrhage. The pain was hypogastric, in some of the attacks there had been vomiting. Radiologically the opaque meal was held up in the caecum and ascending colon for ninety-six hours. At operation an inflammatory mass was found in the central part of the transverse colon. An anastomosis was made between the terminal ileum and pelvic colon. Her symptoms have been entirely relieved.

4 The last case is that of a man, aged 44. He had had attacks of abdominal pain for five months. He was seen during an attack, which commenced suddenly with acute abdominal pain, there was no action of the bowels for eight days. On admission to hospital a tender tumour was palpable in the left iliac fossa. The operative diagnosis was carcinoma of the pelvic colon, and the supposed growth was resected. Examination of the specimen showed the mass to be inflammatory and due to diverticulitis. The iliac anus was closed later.

Questions of surgical treatment may be discussed in relation to these five clinical types.

1 First, in regard to *acute diverticulitis* without complication. The case quoted illustrates what I consider should be the attitude of a surgeon to this type—namely, that unless unequivocal signs of abscess make them appear, and no operation should be done. There is nothing useful to do. Resection of a long length of colon would be a difficult and risky proceeding, and would have to finish with a colostomy. Isolation of the inflamed bowel by wrapping it with omentum is unnecessary, as the bowel can be trusted to isolate itself by adhesions. Lastly, any exploration for a suspected abscess would very likely result in the leaving of a faecal fistula. The one duty of the surgeon is to be on the look out for general and local signs of abscess formation. Unless this occurs the prognosis is good so far as subsidence of the acute attack is concerned. Even if abscess is suspected, delay is best. The case of persistent faecal fistula in my fourth group shows the danger attached to exploration for an abscess buried in a mass of adherent coils of large and small intestine. In this case it is true the adhesions were old and the patient a particularly bad subject, but even in recent cases the risk of serious damage to the bowel wall is considerable.

In one such case, operated on in 1921, I performed caecostomy. I have to admit that the evidence on which the diagnosis of diverticulitis is based in this case is not conclusive, but I believe it to have been an example of the disease.

The patient was a woman, aged 40, who had had symptoms for four weeks—general abdominal pain and blood in the stools. She was confined to bed during this time. The abdomen was distended and a mass was palpable in the left iliac fossa. Temperature 101°F, pulse 116. Her general condition was poor. At operation six days after admission to hospital the sigmoid colon was found transformed into a large inflammatory mass; there was no evidence of new growth. Caecostomy was performed. Her general condition did not improve, watery stools continued with haemorrhage. Death occurred one month after caecostomy.

This case is no test of the value of colostomy in acute diverticulitis, but I believe this to be unnecessary. On this matter there is difference of opinion. Sir Charles Gordon-Watson has said, "In these acute cases colostomy will often be necessary", and again, "In the absence of a definite abscess active inflammation subsides with surprising rapidity after colostomy." This is the only recommendation of colostomy as a measure to be applied in the acute cases which I have met with. It may be that it hastens subsidence, but before adopting it we shall want to know what is the prospect of subsidence in these cases without it. I suspect this prospect to be favourable, and we should, I think, be very sure that it is unfavourable before we adopt a procedure which is so distressing to the patient and which involves many weeks of discomfort before the artificial anus can be closed. Sir C. Gordon-Watson says "After a reasonable interval recovery may be so complete that the colostomy can be closed." For some forms of infiltrative colitis colostomy is the remedy, and without it the disease cannot be controlled, but I doubt very much whether it is the right procedure in the acute colitis which originates in diverticulitis.

II The second class of case, *chronic diverticulitis* without complication, will not often come to surgeons. The treatment has been laid down by the physicians. If such cases come to operation on account of the suspicion of new growth, there is one thing that appears to me to be worth doing. The worst of all the complications of the disease

is a bladder fistula, a complication which has been recorded in quite a number of cases. If the affected coil of colon is lifted out of the pelvis and wrapped in omentum a perforation of the bladder will not occur should an abscess form at a later period. Chronic diverticulitis without complication is not, then, a surgical disease, but if operated on for any reason the bowel should be isolated by omental wrapping, and fixed in the left iliac fossa.

III The accident of *acute perforation* is not likely to be diagnosed precisely before operation. It should be looked upon as a cause of acute peritonitis of not infrequent occurrence, one of the conditions to be borne in mind when the abdomen is opened on account of acute peritonitis of uncertain origin. It is treated on the ordinary surgical lines: the perforated diverticulum is excised and the bowel wall invaginated, drainage being provided as may be necessary. The infection is likely to be of a severe type.

IV In *subacute and chronic perforation* it is best to wait until the abscess is well defined, and, in the second place, to confine surgical treatment strictly to the evacuation of the abscess and the drainage of its site. I am unable to offer any information regarding the prognosis of recurrence of abscess after simple drainage, a question which would be worth while following up. The danger of serious damage to the bowel wall if anything more is done than evacuation of the abscess has already been mentioned. There is not, in fact, any need to search for a sloughed or perforated diverticulum in order to obtain healing.

V Stenosis, when it is certainly known to be secondary to diverticulitis, will require separate discussion in each individual case. There is no such clear indication for operation as in cancer, where it is known with certainty that the stenosis will be progressive. The study of a large group of cases of chronic diverticulitis followed over several years would be of much value. In what proportion of such cases does stenosis supervene? In what proportion of cases of stenosis does acute intestinal obstruction occur?

Mr Lockhart-Mummery writes as follows:

Early recognition of the disease is of the utmost importance but if symptoms of chronic obstruction associated with the formation of a tumour and chronic sepsis are already present, I believe that immediate surgical interference is indicated and that palliative measures at this stage will more than probably result in a disaster from which it will be difficult if not impossible for the surgeon to extricate the patient. As in so many other diseases one sees that the bad results following operation are almost invariably in those cases which have been submitted to operation at a too advanced stage."

The first question to answer in any given case is, Is operation required? If the patient is suffering, in spite of treatment, from recurring attacks of subacute obstruction with griping pain, distension, and constipation, then operation is undoubtedly required.

What operation is to be done? If the disease is so situated and so localized that resection is easy, then this is the operation to choose. But it may be ruled out by two different conditions: first, the disease may be situated so far along the pelvic colon that anastomosis is impossible, and secondly, the extent of bowel involved may be so great that reunion is difficult. It is all the more unjustifiable to submit the patient to an extensive operation involving risks, in that in colostomy we have not *in mere pis aller*, as in cancer, but a remedy for the disease offering at any rate a fair prospect of cure. It proved curative of the stenosis in one of my patients. In stenosis of the pelvic colon when resection is impossible colostomy in the transverse colon seems the proper thing to do. Unfortunately a short-circuit operation will rarely be feasible in view of the usual site of the disease but will be preferred to colostomy under favourable conditions as in case No. 4 of this group.

In three cases in this group, one of which was treated by resection, one by colostomy, and the third by diversion, the necessity for operation was clear. The fourth is a borderline case in which the question of the necessity for operation is one for debate. A male, aged 61, not a good surgical risk, operated on two years ago on suspicion of growth, with symptoms of constipation and recurring griping pain with distension. The sequel is interesting as showing that the stenosis is not necessarily progressive. To-day, although nothing was done, his attacks are of less

severity, and recent radiological examination shows no stenosis definitely less marked than it was two years ago. The diverticulitis and constriction involve the distal part of the pelvic colon, but he has diverticula in the whole of the sigmoid loop and in the lower part of the descending colon, colostomy here would be the operation necessary, but as his symptoms at present show no tendency to increase in severity I advised against any surgical treatment.

At the beginning of this paper I gave the observations supplied to me by Mr. Marver on the localization of diverticulosis on the one hand and of diverticulitis on the other, the bearing of these on the treatment by resection may now be discussed. Is resection generally applicable to cases of chronic diverticulitis without complication?

For two reasons it appears necessary to answer this question in the negative. In the first place it is reported by physicians that the patient can usually be kept in satisfactory health by diet and paraffin. In the second place, the site of the actual disease is often unfavourable for resection and the extent of the bowel involved would necessitate a very extensive colectomy in the great majority of cases. If it is true that the average patient with uncomplicated chronic diverticulitis can be kept in fair health by medical measures, a major operation which is not without its risks does not seem justifiable.

Is resection an operation to be generally adopted for cases of chronic diverticulitis with stenosis? Probably it will be employed more and more frequently in these cases, but it will always, except in a very few cases, be an extensive resection. Resection must go wide not only of the area of diverticulitis, but of any associated diverticulosis. A portion of bowel has to be chosen for anastomosis which is free of developed diverticula, this must be confirmed radiologically, as the presence of diverticula is liable to be overlooked in the course of a laparotomy in a fat-laden bowel. Mr. Marver, in his letter, refers to one such case in which an anastomosis was made in bowel in which diverticula were present, necessitating a further excision after four years of suffering. Before the indication for resection can be settled the value of colostomy in these cases of stenosis will have to be estimated. It may be that if the bowel is kept empty by colostomy the inflammatory condition will subside and the stenosis resolve. In cases of stenosis obviously unfavourable for resection it is the method to be recommended with a fair prospect of its proving curative.

Observations

ON

ULTRA-VIOLET RAY THERAPY *

BY

E. P. CUMBERBATCH, B.M. Oxon., D.M.R.C. Camb.,
M.R.C.P.

MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT
ST. BARTHOLOMEW'S HOSPITAL.

In this lecture I shall doubtless be expected to give a list of diseases which can be relieved or cured by ultra-violet rays, and to say how the treatment should be administered. Thus I shall do, but before I proceed to this part of my lecture I must give an introductory account of the rays and their action on the body. This is necessary, because the subject of ultra-violet ray therapy is far from being standardized, and although I can give some help in the selection of diseases for treatment, and some advice in regard to methods of administration, the general practitioner will frequently be confronted by cases in which he will have to use his own judgement in the treatment of patients. For the benefit of those who desire to practise ultra-violet ray therapy as a "side-line" in their general work I shall lay emphasis on methods and apparatus suitable for this purpose.

The first fact to recall is that ultra-violet rays are not all of the same kind. They differ in their wave-length, and they do not all possess the same biological chemical or physical properties. Those with the shortest wave-

* Abstract of a British Medical Association Lecture delivered to the Southampton Division, March 30th, 1928.

length I shall designate by the number 20, and those with the longest wave-length by 39†. There are rays of every wave-length between 20 and 39. Rays with wave-length shorter than 20 do not concern us, because they do not reach the body. Those with wave-length of 40 are the visible violet light rays. The visible red light rays have a wave-length of 70. Rays with wave-length of 80 and over are the invisible heat waves, sometimes called the infra-red rays. I mention these facts because the ultra-violet lamps also emit these other rays as well as the ultra-violet, and the former possess therapeutic properties too. So when the practitioner exposes his patients to the ultra-violet lamp he administers phototherapy and thermotherapy as well as ultra-violet therapy. This is especially the case when certain types of lamp are used.

When these different rays fall upon the body they penetrate for certain distances, and then they are absorbed. Rays possess energy, and this energy is not lost when the rays are stopped. Either heat is produced or chemical changes occur, depending on the wave-length of the rays and the kind of tissue in which the rays are absorbed. The tissues react to these thermal and chemical changes, and various biological effects ensue. These effects, whether physiological, pathological, or therapeutic, are the outcome of the thermal or chemical changes caused by the rays.

Before we study these effects I must say a few words on the distance to which the different rays penetrate before they are stopped. This is important, because various kinds of tissue lie in the path of the rays, and the distance reached by the latter is dependent on the nature of the tissue as well as on the wave-length of the rays. Ultra-violet rays with wave-length from 20 to 24 are stopped in the stratum corneum of the epidermis. Those with wave-length from 25 to 33 pass through this layer, but are stopped in the stratum mucosum of the epidermis—that is, in the basal epidermal cell. Those with wave-length from 34 to 39 pass through the entire epidermis, but are stopped by the blood in the subepidermal capillaries. Rays with wave-length of 40 (these are the visible violet rays) probably do not penetrate further than the longest ultra-violet rays. On the other hand the visible red ray (wave-length 70) has a much greater penetrating power, and it reaches the superficial strata of the muscles under the deep fascia before they are stopped. The visible green and yellow rays have an intermediate penetrating power. The invisible heat rays have a feeble penetrating power. It is doubtful whether those with the shortest wave-length (80) penetrate much deeper than the sub-epidermal capillaries, while those with longer wave-length do not penetrate as far.

We may now study the action of the various rays on the tissues which absorb them. As I have already said, the rays expend their energy in the production of thermal or chemical changes; their action ends there. The infra-red rays heat the tissues that absorb them. Since their penetrating power is very slight the distribution of the heat is superficial. The maximum temperature is produced on the surface, below the surface the temperature rapidly drops to normal. The visible light rays also expend their energy in the production of heat. By reason of the greater penetrating power of most of these rays they can heat to a greater depth than the infra-red rays. By means of the visible red rays it is possible to elevate the temperature of the superficial layers of muscle under the deep fascia. The ultra-violet rays with the longest wave-lengths (34 to 39) expend their energy in heating the blood in the sub-epidermal capillaries. They have no action, so far as is known, on the epidermis. These are the so-called "long" ultra-violet rays.

The rays which pass through the stratum corneum but are stopped by the cells of the stratum mucosum (25 to 33) produce chemical changes in these cells. These changes are of a destructive nature, and they kill the cells if the rays are sufficiently intense or applied for a sufficiently long time. The dead cells are cast off by the process of desquamation. The separation of the remains of dead

cells is, of course, a natural process, but in physiological states the cells that are cast off have died of old age. The artificial destruction of epidermal cells by ultra-violet rays is followed by certain biological effects. They will be described presently. These rays are sometimes called the "medium length" rays. The rays with wave-length from 20 to 24 (the "short" rays) do not pass beyond the horny layer of the epidermis. Since this layer is composed of dead tissue the rays cannot produce any biological effect in it. If they fell on living tissue they would destroy it, but only to a very slight depth, because their penetrating power is so little. These very short rays can also kill bacteria, but to kill them they must reach the bacteria and not be stopped by overlying tissue. Unfortunately the rays which are most powerfully bactericidal (23 to 24) have a very feeble penetrating power. As the wave-length gets longer the germ destroying power falls rapidly. Consequently we cannot expect ultra-violet rays to destroy bacteria (that is, by direct action) if they lie more than the very slightest depth below the surface.

There is another important chemical change which the rays bring about. This is what is known as the "activation of cholesterol." This substance is present in all growing tissues, and it plays an important part in metabolism. It cannot perform its function unless it is rendered active. Ultra-violet rays possess this activating power. In this way the curative action of the rays in rickets is explained.

Let us now consider the biological effects which follow the physical and chemical changes brought about by the different rays. The invisible heat rays and the visible light rays are thermogenic. Consequently the biological effects of these rays are those of heat. The effects of heat are far-reaching, but the time at my disposal does not allow me to go into the matter. I might mention, however, that it increases the action of those ultra-violet rays which bring about chemical effects.

It is believed that the ultra-violet rays with the longest wave-lengths (34 to 39) have no chemical action on the tissues. It is probable that they are thermogenic. Their biological effects are therefore those of heat. The chemical changes induced in the living epidermal cells by the rays of shorter wave-length are not immediately followed by any visible effect, but after an interval of two to ten hours there develops an erythema. It lasts from a few hours to a few days according to the length of exposure and the intensity of the rays. It then fades away. Desquamation begins after four or five days. The degree of erythema and the amount of the desquamation also depend on the length of exposure and the intensity of the rays—that is, on the dosage. With small doses the erythema is slight and the desquamation is indiscernible. With less small dosage the erythema is more evident and the desquamation is apparent. With heavy dosage the erythema is intense and blisters may form. After a few exposures sufficient to procure a fair degree of erythema there develops in many subjects a pigmentation of the skin. This is due to the formation of a substance known as "melanin" in the basal cells of the epidermis. The most potent erythema producing rays are those with wave-lengths from 29 to 30. The pigment-producing rays are those with wave-lengths from 29 to 33. Rays with wave-length a little shorter than 29 can produce marked erythema without pigmentation.

Accompanying or following these changes in the skin are others in other parts of the body, but the mechanism of their production is not known. We may attribute them to the absorption of substances formed by the action of the rays on the epidermal cells. One of these substances is activated cholesterol. Some of these changes are known. One of these is an increase of the calcium and phosphorus content of the blood; more are absorbed from the alimentary canal. The calcium content of the blood cannot be increased by taking calcium compounds by the mouth. Hence this method of administration is of little value unless the skin is irradiated by ultra-violet light. The red blood corpuscles and haemoglobin are increased by a course of exposure of the skin to the rays.

Another very important change is an increased power of the irradiated body to combat chronic infection. Evidently

† These numbers when multiplied by ten give the actual wave-length in millionths of a millimetre when multiplied by one hundred they give the wave-lengths in what are known as Angstrom units. The shorter figures are less confusing for lecture purposes. The expressions "short," "medium" and "long" when applied to the rays refer to their wave-length.

has shown that the bactericidal power of the blood of animals is increased by irradiating the skin. In man, however, the bactericidal power of the blood is usually high, but it is possible that the sun in power to deal with infection may be due to the absorption of proteins which may be formed by the destruction of the protoplasm of the epidermal cells, the action perhaps being akin to that of protein shock.

The ultra-violet rays, or the products of their action on the epidermal cells, stimulate the nerve endings. In this way the organs of the body and their blood supply may be influenced by reflex action. The dilatation of the sub-epithelial blood vessels is an axon reflex (Dixon). It is likely that there are other forms of reflex action. The internal secretion of the ductless glands may be influenced. The nature of the influence—whether stimulation or depression—and the wave-lengths which are most potent for the production of different effects are at present unknown, and need investigation by the experimental physiologist.

Our knowledge of the physiological properties of ultra-violet rays is insufficient to enable us to forecast with accuracy all the diseases which can be successfully treated. Most of what we know regarding the therapeutic properties of these rays has been learnt by clinical experience. The power of the rays to produce erythema renders them useful in the treatment of inflammation of the skin when the state is chronic and the blood supply poor. The direct bactericidal power of the rays renders them of some additional use in local infection although this action is very restricted on account of the slight penetrating power of the germ-killing rays. The production of local erythema is of use in the treatment of referred pain. Relief may be procured by a process of the nature of counter-irritation. The increased power of the body to deal with infection after administration of the rays renders the treatment of value in cases where the resisting power of the body is enfeebled as in conditions of debility after fevers or local infection. The increased absorption of calcium and phosphorus following general irradiation renders the treatment of value in certain types of bone disease and, if suppuration is present there is an additional indication by reason of the enhanced power of the body to combat infection.

Thus it is mainly by indirect action that the ultra-violet rays bring about therapeutic action. Obviously it must be by indirect action when the disease is deeply situated and beyond the range of penetration of the rays. But even when the irradiated skin is the seat of disease it is almost always by indirect action that therapeutic results are obtained. These results can be obtained by exposing the skin of other parts of the body and leaving out the affected part. It is only in a very few diseases that local treatment of the affected part gives some benefit and even in these the treatment of other areas of the skin—that is, general treatment—is of more value than the local.

Apart from their power to activate cholesterol and increase the absorption of calcium and phosphorus, and perhaps their power to increase the resistance to infection none of the known therapeutic properties of ultra-violet rays are peculiar to them and not possessed by some other agents. Many of the maladies for which the rays are recommended by various workers can be treated just as well, or better, by other physical or electrical or thermal agents. I say this with no intention of disparaging ultra-violet ray therapy. Indeed this form of treatment is capable of yielding results such as a feeling of well being, increased mental vigour, heightened resistance to infection and other good effects in which the *modus operandi* of the rays is difficult to ascertain. Even for the production of results which can be obtained by other methods the rays are convenient and frequently efficient. But if we treat by ultra-violet rays all the cases that do not respond to drugs or expectant treatment we shall not obtain a good balance sheet of success and failure.

With regard to apparatus, there is no lamp which emits heat light, and ultra-violet rays of every wave-length. Different lamps give different selections of all three. So far no essential difference has been established between the results obtained by the use of one type of lamp

as compared with another. The plain carbon arc lamp emits much heat and light, but the proportion of ultra-violet rays is small. Consequently the exposure of the patient is lengthy. By coating the carbon with certain metal salts the exposure can be reduced but white fumes are given off, and these make the air cloudy and the objects in the room are gradually covered with a thin film of white powder. Lamps with tungsten electrodes are open to the same objection, their output is poor in heat rays but rich in ultra-violet rays. The lamp which I recommend is the mercury vapour lamp. Its output is rich in ultra-violet rays but poor in heat rays. It gives off no fumes. It is a clean, cold lamp. It works automatically, needing very little attention. Patients feel no warmth when under it, and they may complain of chilliness during treatment, especially in the winter months unless the room is adequately warmed. A lamp of full size should be chosen. Small lamps are not of much use. Treatment of relatively small areas of the skin can be given by their means, but too much time is occupied when general treatment is required. For local treatment of less accessible regions such as the nose, throat, etc., a special lamp, the water-cooled mercury vapour lamp and quartz rod applicators are used. It is also necessary when long exposures are to be given to cutaneous lesions and exsanguination of the skin is required. This type of lamp will only be needed by those who practise ultra-violet ray therapy as specialists.

I shall now describe what I think is the simplest and one of the most effective ways of administering ultra-violet ray treatment to the patient. It must first of all be realized that *general treatment*—that is, the exposure of the entire skin in large areas of it—is necessary in almost all the diseases which can be benefited by the rays. General treatment is required if the disease is general, even if its manifestations are local. It is necessary even if the disease is local. Only in a very few local diseases is local treatment advisable.

The patient, divested of clothing, except the genitalia should lie horizontally on a couch on his back, his eyes protected by goggles. The lamp should hang three feet above the middle of the body, but a little to one side so that if the lamp should break the hot mercury will not fall on the skin. At his first visit give a two minutes' exposure to the anterior surface. Then turn him on his back and give the same length of treatment at the same distance. Repeat the treatment every other day, increasing the exposure by half a minute at each successive visit until he receives ten minutes to the front and ten minutes to the back. This will complete a course of treatment. This method will, in the great majority of patients, cause little or no erythema, scarcely any desquamation, and no pigmentation. If erythema is caused it is faint and transient, lasting for a few hours only, and disappearing before the next treatment. Should it be noticed when the patient comes for his next treatment, he should receive no further application until it has disappeared, his next dose should be no larger than the preceding one. Should it be found necessary to give a longer course time can be saved by bringing the lamp nearer the patient—say two feet. If this is done the exposure should last, not ten, but five minutes.

Children should receive an exposure of one minute at their first visit, and it should be increased by half a minute at each successive visit. In the case of infants the initial exposure should be half a minute and subsequent exposures should be increased at the rate of a quarter of a minute for each successive treatment. These figures are only intended to provide a rough guide. If, on any occasion, the patient interrupts his course, the practitioner, when resuming the application, must take note of the length of the intermission and reduce the length of the next exposure in accordance. If the interval has been as long as two weeks or more he should resume with the initial dose.

Local treatment can be practised to a limited extent with the mercury vapour lamp. The action of the rays can be restricted to the affected area of skin by shielding the skin in the vicinity by black paper. When giving local treatment it is usually necessary to increase the dosage so as to procure evident erythema. The skins of different

patients vary greatly in their sensitivity to the rays, and the dose which would cause slight erythema in one might produce intense redness and subsequent blistering in another. The best way to avoid this is to make a series of test exposures on small areas of skin. Four small windows, each being one inch square, should be cut fairly close together in a sheet of black paper. The paper should then be wrapped around the forearm and the four areas of uncovered skin exposed to the rays, the lamp being at a distance of two feet. These areas should receive one, two, three, and four minutes' exposure respectively. The same hour next day the areas should be examined. The length of exposure to the area in which there is distinct redness should be the length of treatment to the affected region.

The diseases which may be treated by ultra-violet rays I shall classify in three groups. The first includes those in which the treatment will always effect a cure. The second contains those in which the treatment will generally effect a cure, either alone, or in conjunction with other forms of treatment. The third includes a large number of diseases or cases, mostly common and obstinate, for which the treatment is now being tried. In these diseases the insufficiency of experience renders it difficult to say whether the rays are of real use. To these groups I shall add a fourth, which will include those in which the treatment is likely to produce harmful results.

Group 1—The disease which must be given pride of place in ultra violet ray therapy is rickets. For this the treatment may justly be regarded as a specific. I do not know any other disease for which it is a specific, although tetany and laryngismus stridulus—when occurring in rickety children—are said to respond equally well.

Group 2—In this group I would place first the cases of infants who are unable to assimilate their food, and who consequently waste. If no organic disease is present the major number begin to thrive and put on weight. The treatment must be applied very cautiously and minute doses given. Children who have been the subjects of the fevers which commonly occur during their early years, but are left in a weak debilitated state, respond well to the treatment. Their health improves and they gain in weight. Nasal and bronchial catarrh lessens or disappears, and aurial discharge loses its offensive character and may disappear. If the last-mentioned trouble is present, that most valuable form of treatment, zinc ionization, must not be forgotten. Adults who are left in a debilitated state after influenza or similar types of fever improve greatly after ultra violet irradiation. In surgical tuberculosis the rays can play a valuable part in bringing the disease to an end, but additional treatment is generally required, such as surgery, application of splints, etc., and residence at the sea or in the country are necessary for most cases. For this reason the treatment of surgical tuberculosis by ultra-violet rays in large towns is frequently unsuccessful. In dermatology the disease which is most often treated by the rays is lupus vulgaris. General treatment is more effective than local, though they can be combined with advantage. Local treatment requires the water-cooled lamp. The electro-thermic methods are very useful in local treatment, but general treatment should not be omitted. Other infective diseases of the skin, such as impetigo contagiosa and acne vulgaris, respond well. Patients who are liable to boils and carbuncles may be treated by the rays with advantage. Their low resistance to infection by staphylococci can thereby be increased. In seborrhoea I have had some good results in obstinate cases. In true eczema success is not often obtained. The so-called "weeping eczema" (which is really seborrhoea) improves under the treatment, and the "trade eczemas" (which are really forms of dermatitis caused by chemical irritants) can be cured if the causes are removed. Non-specific indolent ulcers should receive a trial of the treatment, both local and general, and success will often be obtained. Erythema pernio is said always to respond to the rays, but I prefer diathermy. In true psoriasis I have had no success with ultra-violet rays. Some cases of pruritus ani and vulvae can be freed from the itching. These cases require local treatment, and when it is given every particle of mucus and exudation and previously applied unguents must be removed. Some

writers have described good results in the treatment of erysipelas by the rays. I have had no personal experience. In alopecia areata the hair grows again after a course of local treatment by the rays. A long course may be required.

Group 3—This includes a large number of chronic maladies and obstinate cases which resist drug treatment. The "rheumatic material," such as chronic fibrositis and arthritis, with which the various departments of physiotherapy are so plentifully supplied, has been treated by the rays, but I have had infinitely better results—at any rate in women—by pelvic diathermy. Treatment of chronic fibrositis and arthritis by the rays will generally be followed by disappointment. The ultra-violet rays have been tried in infection of the uterus and its adnexa and the pelvic supporting tissues, erosion, and some forms of dysmenorrhoea, but here again pelvic diathermy gives far better results. In obstinate cases of sciatica and brachial neuritis I have had little success with the rays after other forms of physiotherapy had failed, although it is possible that the cases which had been cured by the latter would have responded to the rays. Hyperpnea, chronic bronchitis, bronchial asthma, hay fever, Raynaud's disease, acrocyanosis, and other diseases are being treated by ultra-violet rays, and success has been claimed by different writers, but sufficient experience has not been gained to enable a definite statement to be made regarding the therapeutic value of the rays in these diseases.

Group 4—This includes the diseases and patients for which the rays should be administered with extra caution or not at all. Patients with general pyrexia should not receive ultra-violet ray treatment. In acute local infection the rays should not be applied locally, nor should general treatment be given if the body temperature is raised. If pus is present the treatment should not be given until it has been evacuated. If it is suspected, the treatment should be postponed. In pulmonary tuberculosis the treatment should not be given, except by an expert, quiescent phthisis has been rendered active. It is inadvisable to apply the rays to patients who are suffering from failing hearts or who are the subjects of Bright's disease. It is generally inadvisable to give the treatment to very old people. During menstruation ultra-violet ray treatment should be omitted.

In concluding a short lecture on a very large subject I would insist on treatment by ultra-violet light being under the direction of medical men. Unqualified people, even if they are trained, can only administer the rays, but the doctor can employ them to treat disease.

CONGENITAL OESOPHAGEAL OBSTRUCTION

BY

A. LAWRENCE ABELL, M.S., F.R.C.S.,

SURGEON TO THE KENSINGTON GENERAL HOSPITAL, ASSISTANT SURGEON TO THE WOOLWICH WAR MEMORIAL HOSPITAL.

CONGENITAL malformations of the oesophagus are by no means extremely uncommon, and usually manifest their presence within a few days of birth, almost all prove rapidly fatal. Life may, however, be saved in some of the rarer cases by prompt intervention, and I propose to give details of a case of complete oesophageal obstruction, operation, and recovery, followed by pyloric stenosis, a second operation, and recovery. Before doing so I will outline the development and the congenital malformations of the oesophagus.

DEVELOPMENT

From the primitive foregut the pharynx, oesophagus, and stomach are developed. In the third week the oesophagus is a mere sphincter, or constriction, between the pharynx and the stomach. When the neck is differentiated during the second month the oesophagus undergoes a rapid elongation, the chief factor in producing this elongation is the development of the lungs and pleural cavities, whereby the stomach is pushed backwards into the body cavity. Up to the third week the trachea and oesophagus form a single structure, the lung buds have not yet appeared. There is, however, a histological differentiation of the two parts, which will be described later.

Separation of the oesophagus from the trachea takes place during the third and fourth weeks by the growth of two lateral septa, which eventually meet and fuse in the mid-line to form a partition from which is differentiated the posterior (membranous) wall of the trachea and the anterior wall of the oesophagus (Fig 1). The last portion to fuse is the caudal extremity of the partition—that is at the level of the bifurcation of the trachea. In the fourth week the lung-buds arise from the distal extremity of the respiratory tube, and by their rapid increase in size cause the elongation of the oesophagus referred to above.

Differentiation of the Histological Structure

In a 4 mm embryo the oesophagus is an epithelial tube, flattened from side to side, with a ventrodorsal lumen. It is lined with two layers of cells, the nuclei nearest the lumen showing mitotic figures. The upper portion of the oesophagus shows a slightly different structure, here the dorsal portion of the tube is lined with a single row of cells, while the ventral portion shows three or four layers, this thickened portion is destined to form the respiratory tract. The tube is surrounded by a mass of undifferentiated mesenchyme.

After the trachea and oesophagus have been separated by the fusion of the septa the oesophageal lumen becomes greatly narrowed by a proliferation of the epithelial lining, some authorities consider that it becomes entirely obliterated; others maintain that the original lumen is never entirely lost.^{2,4} The former view is probably correct. In 20 mm embryos vacuoles appear in the epithelium. There are two theories as to their origin: (1) that they are due to accumulation of intracellular fluid, (2) that they are due to an active moving apart of the cells through a transference of mitotic activity from the inner to the outer layer of cells. The latter is regarded as being the most probable explanation of their formation. The result is an enlargement of the lumen due to coalescence of neighbouring vacuoles.

FIG. 1 TO 9.—Diagram showing congenital anomalies of oesophagus.

CONGENITAL MALFORMATIONS

There are seven types of congenital malformation:

- 1 Total absence of the oesophagus
- 2 Doubling of the oesophagus
- 3 Oesophago-tracheal fistulae
- 4 Partial obliteration of the oesophagus
- 5 Diverticulum formation
- 6 Simple congenital strictures
- 7 Membranous or valve-like strictures.

1 *Total Absence of the Oesophagus*.—This occurs only in acardiac monsters, in whom the head also is usually missing and this type is of no importance.

2 *Double Oesophagus*.—Blasius (1674)⁵ records a case of a newborn infant in which the middle two-fourths of the oesophagus was double; this, however, did not cause any obstruction. I can find no record of any similar case.

3 *Oesophago-tracheal Fistulae*.—As was stated in the section dealing with the development of the oesophagus the two lateral septa of the cephalic extremity of the foregut which meet and fuse in order to differentiate the upper half of the oesophagus from the trachea have their point of ultimate fusion at the lower end of the trachea. In this situation they may fail to meet and hence an oesophago-tracheal fistula results. (a) If the oesophago-tracheal septa develop in their normal plane apart from the fistula, both organs are normal (Fig. 2). It rarely

happens that a fold of mucous membrane covers this opening. (b) If the plane of development of the oesophago-tracheal septum is faulty, the latter becomes attached to the posterior wall of the foregut and so leads to obliteration of the upper part of the oesophagus, together with a fistulous communication of the lower part of the oesophagus with the trachea.⁶ This is the commonest congenital anomaly of the oesophagus (Fig. 3).

4 *Partial Obliteration of the Oesophagus*.—(a) Simple blind ending of the upper part of the oesophagus may occur, possibly as a result of a deviation in the lines of development of the two lateral septa. In these circumstances the proximal end of the lower part of the oesophagus is blind also. Another explanation is that the rapid growth of the lung buds has ruptured the continuity of the slender tube which is the primitive oesophagus.⁷ It sometimes happens that the upper and lower blind ends are united by a strip of muscle tissue (Fig. 4). This would appear to be due either to a rupture of the inner layer of cells or to a failure of the epithelium in a portion of the oesophagus to undergo vacuolization, and therefore the lumen, which, according to some observers, has been entirely obliterated at one stage of development, never again becomes patent. The outer layer of cells, however, persists, and forms a thin strand of muscle. (b) Obliteration of the oesophagus may occur only from the level of the tracheal bifurcation downwards, the oesophagus above this level being normal (Fig. 5).

These varieties of malformation of the oesophagus are of interest because of their frequency and because of

the embryological factors concerned in their production. Clinically, however, they are of small importance because no treatment is of any avail. These anomalies are often associated with other congenital malformations—for example Meckel's diverticulum, imperforate anus, and duodenal atresia.

In Types 3 and 4 above severe interference with swallowing is occasioned; gurgling sounds are heard when fluid enters the trachea as soon as the infant swallows, followed by violent attacks of coughing and vomiting. If feeding is persisted in the child may be asphyxiated or pulmonary complications may supervene. Death occurs either from these or from inanition.

Curable Types

I shall not describe the varieties of congenital anomalies of the oesophagus which, although very rare, yet are of great clinical importance because their early recognition and prompt treatment may make all the difference between the life and death of the patient.

5 *Congenital diverticulum* at the pharyngo-oesophageal junction is extremely rare, occurs in the same position as the acquired Zenker's pulsion diverticulum, and eventually produces similar symptoms. It is possibly atavistic in origin, being present normally in the hog and some other animals.^{8,9,10} It differs from a true Zenker's diverticulum by having a complete muscular covering, but its treatment is the same as that of the acquired form.

6 *Simple Congenital Strictures*.—In these cases there is a definite narrowing of the whole circumference of the oesophageal wall at one or more places. This type is very uncommon. The narrowed portion may be either circular and confined to only a small area (Fig. 6) or may extend through more or less of the length of the oesophagus (Fig. 7). Rarely is the upper end of the gullet the affected region;^{11,12} more commonly it is the lower segment.¹³⁻¹⁵ The symptomatology is similar to that of the succeeding variety.

7 *Membranous or Valve-like Strictures*—Membranous or valve-like strictures are, according to Kraus,¹² very rare. The membrane may form a ring-like fold (Fig 8) or a complete diaphragm (Fig 9), and is generally situated a very short distance above the cardia. The condition has been known to be associated with an oesophago-tracheal fistula, but may be the only abnormality.

The *etiological factors* concerned in the formation of simple congenital strictures and of membranous strictures, whether complete or incomplete, would appear to be one or more of the following errors of development:

1 The "mere sphincter" between the pharynx and the oesophagus in a 4 mm embryo referred to above does not elongate equally, but leaves a stenosis of one portion of the canal.

2 The obliterated tube fails to canalize at one place.

3 Although canalization occurs, yet the inner layer of cells fails to transfer its mitotic activity to the outer layer, and therefore a local area of oesophageal wall remains without coalescence of the local venules, and stenosis results.

SYMPTOMS AND DIAGNOSIS

In both simple congenital and annular membranous strictures cases have been recorded in which symptoms were not produced until, after weaning, the child was found to be unable to take solid food, which was almost immediately regurgitated. By feeding solely upon fluids, chiefly milk, life has been maintained, and patients have lived for many years before the true nature of the lesion has been discovered. These patients are very underdeveloped and thin, and males are said to show only slight masculine characteristics.

On the other hand, depending upon the degree of atresia, symptoms of oesophageal obstruction, notably dysphagia and the regurgitation of fluids, may make their appearance as soon as fluid is given to the newborn infant.

If the membranous stricture is not annular but in the form of a complete diaphragm, symptoms of complete oesophageal obstruction are always present from birth. The precise diagnosis of the actual type of oesophageal malformation which is present can only be arrived at by means of a careful x-ray examination and oesophagoscopy, and should not be left until the *post-mortem* examination is reached.

COMPLICATIONS

If left untreated all cases of complete occlusion die of inanition, also the more severe stenoses. With an inadequate lumen the stagnated food may produce a marked oesophagitis in the portion of the oesophagus which is dilated above the stricture. The ulcerative process may actually cause perforation. In rare instances a pressure diverticulum is formed above the stenosis, as in one of my cases. Probably apart from this secondary dilatation of the oesophagus a true congenital dilatation does not occur.

TREATMENT

(a) For Simple Congenital and Annular Membranous Strictures

Simple strictures are best treated by slow gradual dilatation by means of bougies. This produces a more permanent result, and much less damage, than when dilatation is performed rapidly. Rapid dilatation causes ulceration at the site of the lesion, and is followed by fibrosis, contraction, and a tighter stricture than was present before treatment commenced. In addition, too rapid dilatation may cause perforation or rupture of the oesophagus.

Treatment, therefore, consists in the passage of carefully graduated bougies. At the first sitting a bougie which only comfortably fits the stricture is passed under direct vision through the oesophagoscope. At subsequent sittings, which should take place once or twice a week, bougies may be passed blindly provided there is not a great deal of dilatation of the oesophagus or diverticulum formation above the stricture. Commence with a bougie of the same size as the one passed through the oesophagoscope, and when this has remained *in situ* for a few minutes replace it by a bougie of one size larger, and at each subsequent sitting pass, if possible, one bougie a size larger

than the largest previously used. In no circumstances should any force be used.

Annular membranous strictures may respond to similar treatment, but, as with this type of stricture considerable dilatation of the oesophagus is usually present, and the lumen is always eccentric, the bougies must invariably be passed under direct oesophagoscopy vision. This type of stricture lends itself to internal oesophagotomy, whereas with simple strictures involving a considerable length of the oesophageal canal this procedure is fraught with much danger. A ring-like stricture may also be treated successfully by electrolysis.

In an emaciated, dehydrated patient, or if in spite of great care and patience improvement does not occur, a gastrostomy is necessary. This allows rest to the oesophagus, permits feeding of the patient, and a retrograde oesophagoscopy may be performed. By this means, or by peroral endoscopy, a filiform bougie to which is attached a silk thread is passed through the stenosis. The thread is drawn upwards or downwards, as the case may be, until one end projects out of the mouth and the other through the gastrostomy opening. Each end of the thread is attached to the two ends of a fine piece of rubber tubing, and therefore a continuous or endless chain is present. By means of the thread the tubing is pulled hard enough to render the diameter of the rubber small enough to pass the stenosis. When tension on it is relaxed its length is diminished and its diameter increased, and it then exerts continuous pressure on the stricture and causes further dilatation. The rubber is left in position for an hour or

FIGS 10 AND 11—Congenital stricture of oesophagus treated by rubber tube.

two every day, and then by pulling upon the thread the rubber is displaced from the oesophagus and its place taken by the thread. Every few days the tubing must be replaced by one of larger calibre until sufficient dilatation is obtained (Figs 10 and 11).

(b) A complete membranous diaphragm in a newborn infant may be perforated by means of the oesophagoscope or a bougie. In this way I have recently treated with success an infant less than two days old suffering from this condition.

CASE OF COMPLETE MEMBRANOUS DIAPHRAGM

The patient was a female child who was born on the evening of January 18th 1928. The mother was a primipara and the labour, which was not abnormal in any way lasted twenty-one hours. The child weighed 7½ lb and appeared to be perfectly healthy.

Throughout the whole of the following day attempts were made to feed the child at regular intervals. At no time would she suckle the breast and when given teaspoonfuls of milk and water the infant appeared to have great difficulty in swallowing and regurgitated the fluid as soon as it had been taken. On one occasion only was there a small quantity of blood, but on each occasion she coughed and choked a great deal and became very agitated.

I saw the child with Dr Henry Robinson about noon on January 20th when she was just forty-two hours old. Outwardly she appeared quite normal but on feeding with a teaspoonful of water she coughed, became cyanosed, retched and retained none of it. The child obviously had a congenital abnormality of the oesophagus and this was most likely to be in the nature of an oesophago-tracheal fistula. The infant was twenty-five miles from London and x-ray examination was not immediately available but having an oesophagoscopy outfit I decided to perform oesophagoscopy forthwith. This was done without of course, any

anæsthetic using a 4 mm. tube (Jackson's pattern) which passed quite freely down to and beyond the level of the bifurcation of the trachea. About 1 in. below this level, however, the tube became obstructed by a glistening membrane with a mother-of-pearl appearance which was at first thought to be inspissated mucus. Careful snabbing, however, showed it to be a solid structure and no opening could be found in it (Fig. 12).

By pressing firmly with the end of the tube the membrane was ruptured and normal oesophageal mucosa was seen below it. Gastric mucus was easily recognized after the tube had been pushed about 1 in. further. On withdrawing the oesophagoscope a few drops of blood obscured the view of the wall of the gullet at the level where the membranous diaphragm had previously been seen. No other abnormality was detected in the pharynx, larynx, or oesophagus.

One ounce of exhausted breast milk was now given to the infant who swallowed it normally and retained it. This appeared very satisfactory and we thought it worth while to investigate the case still further by means of x-rays. With Dr. Robert Knox we examined the infant the same afternoon with the fluorocent screen while she swallowed an emulsion of bismuth and a definite narrowing of the lumen of the oesophagus together with a slight delay in the passage of the bismuth was noted about an inch above the stomach. No other abnormality of the upper alimentary tract could be detected and we were able to give a fairly good prognosis. This was borne out by the fact that the child, although she persisted in refusing the breast, swallowed and retained fluid normally and scarcely vomited again. Temperature, pulse and respiration were normal throughout.

The baby, which had lost about 3 lb. in weight, made steady progress until four weeks later when she weighed 8 lb. She then began to vomit forcibly through both the nostrils and the mouth. A gastric tumour was visible and a pyloric tumour palpable on the second day of these symptoms and hypertrophic pyloric stenosis was diagnosed. Laparotomy on February 18th confirmed this and no other abnormality of the stomach or duodenum was found. Rammstedt's operation under gas and oxygen anaesthesia was followed by an uninterrupted recovery. For some considerable time after this the child was difficult to feed but has now settled down and is doing well at 5 months old she weighed 11½ lb.

The points which I wish to emphasize with reference to this case are:

- 1 So far as I know, this case is unique. I can find no record in the literature of any previous case which has survived.
- 2 Congenital oesophageal malformations are not so rare as might be supposed.
- 3 The symptoms of all varieties are almost identical.
- 4 Some cases which are curable are probably diagnosed as being incurable.
- 5 A careful examination by means of prompt oesophagoscopy, with or without x-ray examination should lead to a cure of a number of cases for which at present no treatment is undertaken.

PRIMARY SPASMODIC DYSMENORRHOEA AND ITS TREATMENT

BY

C. W. A. FRYER, M.B., B.Ch.,
Westcliff-on-Sea

PAIN at the commencement of the menstrual period is very common, and is met with in varying degrees of intensity. It may be only a transitory sensation, or it may be severe enough to force the patient to bed. The more severe types present a trying problem, not only by reason of the distress, but also because of the interference with the patient's livelihood as a result of her inability to follow her normal occupation, which may be more important from her point of view. Patients are nearly always nullipara, though there are exceptions.

In typical cases the pain may come on a few hours before, and end with the menstrual flow, or it may continue for forty-eight hours of that period. Nearly always cessation of pain coincides with a free flow. There are, of course, cases in which pain lasts longer, even throughout the period, but in suggesting a treatment it is better to consider only the typical cases which constitute the majority. The atypical yield to treatment devised on the same lines.

The patients as a rule are anaemic and listless, but the rapid improvement which follows removal of pain suggests that these are, in a large part, secondary symptoms. The increased menstrual flow which follows the usually sudden cessation of pain indicates that an obstruction has been overcome. That obstruction occurs at the junction of the body of the uterus with the cervix. When menstruation commences, in the normal subject, the potential uterine cavity becomes a real one through separation of its walls by accumulating menstrual fluid. Real resistance is met

with, however, at the junction of the body with the neck, and this is overcome by a "lifting" of the body as a result of increasing intrauterine tension, so that a continuing line through the cavity of the body and that of the cervix tends to become one straight line. When this happens the loss becomes free and, tension in the body having dropped, there is no pain. Should the uterine body find difficulty in performing this movement intrauterine tension steadily increases above the normal, and a stage is reached when spasmodic muscular contractions are set up in the uterine wall with resulting pain, the condition now constituting spasmodic dysmenorrhoea.

That a body such as the uterus does tend to assume but one position on distension can be shown experimentally. If the stem of a small rubber balloon is placed between two fingers, at the junction of the bulbous part with the stem the body lying deflated on the back of the hand, it will be found on inflation that a line drawn through the centre of the bulbous portion to its junction with the stem tends to form, and in this case actually does form, a straight line continuous with one drawn through the centre of the stem, in its length. If, before inflating, a small area of the bulbous portion, near its junction with the stem, is painted with rubber solution and allowed to dry—this area representing the portion of the uterus on the side on which it is flexed—the lines drawn as before will not form a continuous straight line when the balloon is inflated. If these lines followed the course of potential channels a fluid would be obstructed at their junction to a degree dependent upon the angle.

Again, the operation of dilatation for menstrual pain by the very type of instrument used merely "straightens" the uterus, and for success depends upon that position being maintained. Following pregnancy a cure often results, because here again the same thing occurs, though the hyperplasia in the uterine wall tends to overcome any lack of elasticity present.

It is clear, accordingly, that inability of the body to assume easily this new and normal position at the commencement of menstruation must result in increased intrauterine tension due to accumulation of menses and turgidity, and that as a result the musculature falls into painful spasm. Two factors are at work in preventing a desired state of affairs, and they may operate separately or in varying degrees of combination. These factors are (1) the elasticity and flexibility of wall, in the angle formed between body and cervix, is below normal, and (2) too acute an angle is formed by the body with the cervix. Intrauterine tension has to overcome one or both of these factors, and if it does so completely relief from pain follows. Just before relief occurs the uterine angle has reached its ideal or "essential to flow" degree, and the vital point in treatment is to ensure the uterus contracting in this position. In my opinion all efforts at causing contraction should, if possible, be commenced just before this tension is released, because immediately afterwards there is a sudden return to the "resting" or intermenstrual state.

I had thought that perhaps a natural rhythmic increase in general blood pressure governed the menstrual flow, and that the cases of amenorrhoea which quickly responded to tonics supported this theory, but continued blood pressure recordings yielded no evidence, so I am convinced that the increased intrauterine pressure is purely the result of local conditions.

I have discussed the causes of spasmodic dysmenorrhoea, as I see them, at some length, because so much depends on their being thoroughly understood. Treatment is simple, but the results I have obtained as the result of this reasoning over a period of four years are very good, patients have remained free from pain for varying periods up to three and a half years.

Successful treatment depends on increasing intrauterine congestion and distension so as to get as much "straightening" of the uterus and as great an "essential to flow" angle as possible, the uterus is then made to contract in this position. It is necessary to establish very carefully the time when the pain commences, and when it ceases, with relation to the commencement of the menstrual flow.

It is very advisable to warn the patient that the effects of the actual treatment will only be noticeable at the periods succeeding the one treated. In the pain at this period for which the patient first consults you there are only the time-honoured sedatives.

In outlining this treatment I will assume that the patient comes for treatment between the periods, but it is possible to commence at any stage. A good general tonic should first be given, and be continued up to the commencement of the period. One such as the following is very satisfactory. Ferri et ammonii citrate 1 drachm, liq. arsenicalis 1 drachm, aq. chlorof. to 6 oz., one tablespoonful to be taken in water three daily after meals.

When pain commences, whether the menstrual flow has started or not, a hot hip bath is ordered, and for the pain aspirin, phenazone, and bromides may be prescribed. Morphine is unnecessary, the patient will have had attacks before the present one and her desire for treatment is only a very faint justification for its use.

Having ascertained how long the pain lasts as a rule the following mixture is commenced a few hours before the pain ceases, the prescription is Liquid extract of ergot 30m, pot. brom. 5 grains (or tr. chlorof. et morph. 3m), water to 1/2 oz. If the pain lasts thirty-six hours or more the mixture is given two-hourly for six hours previous to its cessation and four-hourly afterwards. If it lasts for about twenty-four hours commence about four hours previous to its cessation, if much less than twenty-four hours commence just before cessation, but give only at four-hourly intervals.

The patient should not be permitted to keep the medicine by her for long, because the instability of these preparations is notorious. The age of the patient does not affect this dose of ergot, though for patients under 18 it is unnecessary to give it more often than every four hours. Frequently the following period will be free from pain, but the patient should be advised to continue the tonic between periods, to come for the ergot mixture before the period, and to repeat the treatment if pain recurs. As a rule up to four treatments constitute a maximum. If pain recurs an exact record should be kept of its relative time, this will give guidance as to variation in the time at which you must give the medicine. The time of cessation of pain may vary under treatment in many cases, it must be observed, and the inferences translated into action.

In one type of case a certain number of months remain free and then there is a relapse. Some of these can be corrected, if the duration of the pain is known, by an injection of posterior pituitary extract, about four hours before its cessation, the medicine being used as before. The treatment indicated greatly reduces the cases in which operative intervention may be necessary, there will still remain a few, in which the mechanical solution (dilatation, or the more natural one, pregnancy) must be considered. For example, a patient may have been married for three or four years without conception having occurred, this may indicate obstruction in the length of the canal, and heroic measures may be necessary, but my advice is "try medicinal treatment first."

With special reference to pregnancy, when faced with unsatisfactory results following the prevailing methods in the treatment of unmarried women, I refrain from falling back on the idea that as a last resort it is right to suggest that this is "Nature's cure." It may be so, but what a wealth of impotence on the part of the practitioner is implied! Moreover, the results will sometimes be most unsatisfactory, and there is the risk of precipitating a union which may be followed by misery in other respects.

One of my patients, a woman aged 38, had been so advised, but a baby, born thirteen years ago, brought no relief. The two periods following her first medical treatment have been the only ones in her menstrual life free from pain.

In conclusion, let me repeat that what has been described is the treatment of typical cases, since these preponderate among a large number of women whose livelihood is affected, I make no other excuse for stating an unfinished case.

A CARBOHYDRATE DIET FOR HYPERTHYROIDISM

BY

HENRY MOLL, M.D., M.R.C.P.,

MEDICAL TUTOR AND REGISTRAR, UNIVERSITY OF LEEDS

Hitherto not enough importance has been given to diet in Graves's disease, treatment being focused mainly on the thyroid gland. There are, however, important reciprocal relations between the thyroid gland and the gastro-intestinal tract of which we have little knowledge yet, but which nevertheless demand a closer study of dietary in hyperthyroidism. Thus, various manifestations of nervous dyspepsia are not only common symptoms of hyperthyroidism, but may also precede for a variable time the other cardinal signs. This was borne out by a statistical study of the more important symptoms in a series of sixty-nine cases of Graves's disease in which the symptoms were tabulated both in order of frequency and time of occurrence.

TABLE I—Percentage Incidence of Symptoms in Hyperthyroidism

Palpitation, shortness of breath and weakness	100 per cent
Mental excitability and loss of weight	85
Diarrhoea	75
Swelling of the neck, exophthalmos and tremor	70
Indigestion	50

TABLE II—Order of Occurrence of Symptoms in Hyperthyroidism

A—Early Symptoms	B—Later Symptoms
1 Weakness	5 Swelling of the neck
2 Indigestion	6 Mental excitability
3 Shortness of breath	7 Diarrhoea
4 Palpitation	8 Exophthalmos and tremor

From these tables it will be seen that indigestion—and under this term are included nausea, vomiting, anorexia, gastric discomfort and sometimes pain—not only occurs in half the cases of Graves's disease, but, when present, is usually a very early symptom and accompanies other prodromal signs of hyperthyroidism such as loss of weight, weakness, shortness of breath and palpitation. Moreover, in 50 cases of hyperthyroidism in which fractional gastric analyses were carried out it was found that gastric motility and secretion become profoundly modified in exophthalmic goitre.

The rate of gastric emptying is exceedingly rapid, often so rapid that very little is to be found in the stomach at the end of an hour, the average emptying rate being fifty-five minutes in cases of achlorhydria and ninety minutes in cases of hypochlorhydria. This rapid emptying of the stomach may be largely explained by the achylia so commonly found in Graves's disease and which was actually present in 22 cases out of 50 examined. The hurrying of food which takes place in hyperthyroidism, together with the lack of secretion, must to a certain extent prevent digestion occurring in the stomach and may afford an explanation of the frequency of digestive troubles in exophthalmic goitre. Some generalities may therefore be drawn from this with regard to dietary.

As the intestines probably have to act vicariously and digest food for the stomach, it is important to arrange the diet so that it can easily be acted on by the intestinal juices. Proteins, being largely digested by the stomach, should be given only in easily digestible forms—for example, brains, scraped beef, sweetbreads, chicken and fish—and their amount reduced to a minimum as they can be positively harmful by stimulating physical and mental activities and thereby increasing the strain on the thyroid gland.

The food must be broken up in fine particles and given as far as possible in liquid form. Six to seven small meals should be given at intervals of two to three hours rather than three full meals in the course of the day. The caloric value of the diet should be high with a tendency towards superalimentation in order to keep pace with the raised metabolic rate.

Amongst the protein spacers to be substituted in the diet, fats are unsuitable. Hyperthyroid patients seldom tolerate fats and these should be given in the more digestible forms, such as the artificial fatty foods. Carbohydrates, on the contrary, may be freely given, as they are as a rule, well tolerated by patients suffering from hyperthyroidism, and may be given in sufficiently large amount to raise the caloric value of the diet to a high level. As a matter of fact I have found carbohydrates act so favourably in hyperthyroidism that the following dietary containing a large excess of carbohydrates was adopted in conjunction with other forms of medical treatment of Graves's disease. The diet is of a caloric value of 2,700 calories, and contains roughly 80 grams of protein, 50 grams of fat, and 440 grams of carbohydrates.

Diet Sheet of a Full Carbohydrate Diet for the Treatment of Graves's Disease

6 a.m. (Breakfast)—Oatmeal porridge 4 oz. tea with cream-bread (two slices) butter 1/4 oz. honey or jam 1/2 oz. fruit 4 to 6 oz. (bananas, grapes, plums, prunes, apples, pears, cherries, apricots, oranges).

8 a.m.—Proprietary food 6 oz. (Benger's food, Mellin's food, Horlick's malted milk, banana, Robinson's groats or patent barley, etc.) bread two slices.

10 a.m.—Milk 8 oz. with Mead's dextrimaltose.

12 a.m. (Lunch)—Meat 2 oz. (scraped beef, brain, sweetbread, chicken, pigeon, rabbit) or fish 2 1/2 oz. (cod, haddock, whiting, lake plaice, etc.). Vegetables—Group 1 4 to 6 oz. (potato, artichoke, parsnip, peas, carrots, onions, beetroot, turnip). Group 2, 3 oz. (broccoli, Brussels sprouts, cabbage, cauliflower, leeks, spinach, tomatoes, celery, lettuce). Bread (two slices) milk 6 oz. milk pudding 4 oz. (rice, arrowroot, cornflour, sago, tapioca).

3.00 p.m. (Tea)—Same as breakfast but without porridge.

6 p.m. (Supper)—Proprietary food 6 oz. bread two slices, one egg.

10 p.m.—Milk 8 oz. with malt extract or milk sugar.

Extras—Cream up to half a pint or fatty artificial foods (cod liver oil, cicemalt, etc.) 1 oz. three daily.

Fats in the form of cod-liver oil and cream are added later as extras, thus raising the caloric value of the diet to over 3,000 calories, while a liberal amount of dilute hydrochloric acid should be given in the form of a long drink to be sipped during mealtime to counteract the achylia so often present in exophthalmic goitre. Patients take the diet particularly well and baring cases in which it may cause or aggravate a flatulent dyspepsia can usually be kept on it for quite a considerable time without tiring of it. Often the appetite improves remarkably.

In watching the progress of the case the extreme variability of the appetite so often present in Graves's disease has to be taken into account, as periods of anorexia alternate with periods of hunger, vacillating with the emotional instability. The improvement is shown by the lessening of the nervous symptoms, by the fall of the pulse rate and of the pulse pressure, and by the rapid increase of weight. Some patients gain as much as 10 lb. in a fortnight. The patients should be kept on the diet for several months and afterwards revert to a normal diet by degrees, first by the addition of fats and then of proteins.

It may be objected that it is unsafe to give a full carbohydrate diet in a disease where there is often a lowered sugar tolerance. This is often revealed by the response which is observed in exophthalmic goitre to a sugar tolerance test although there may be only a latent defect of sugar storage without glycosuria. Thus in three cases of hyperthyroidism taken at random, but sugar-free on a basal diet, one gave a normal response to a glucose tolerance test (50 grams) another showed a lag type curve, and the third had a high threshold and a high rising curve typical of diabetes mellitus. Apart from these cases in which the disturbance of carbohydrate metabolism is only detected by a sugar tolerance test there are other cases of hyperthyroidism with glycosuria of varying degrees, from severe forms with marked denutrition and ketosis to milder ones of intermittent glycosuria. In the light of these findings a full carbohydrate diet would at first appear to be inadvisable in Graves's disease. However, glycosuria very rarely occurs after a carbohydrate excess diet, and when it does the glycosuria very often soon disappears after pushing the diet still further.

While certain cases of hyperthyroidism with glycosuria have to be treated on true diabetic lines, others can be

given starchy food with impunity, and it is remarkable how glycosuria rapidly disappears on full carbohydrate diet, as is shown by the following case

A woman, aged 22, had had an enlarged thyroid gland since the age of 15, but without symptoms of hyperthyroidism. Six months ago the thyroid gland increased in size, and for the first time signs of hyperthyroidism made their appearance—namely, breathlessness, sweating, exophthalmos, and tremor. Examination revealed a large adenomatous thyroid gland, ocular signs, exophthalmos, tremor, and a high pulse pressure. At this time there was no glycosuria. The patient while in hospital developed diphtheria and had to be removed to a fever hospital. On her return a month later the general symptoms of hyperthyroidism seemed somewhat intensified and glycosuria had appeared. Thereupon a glucose tolerance test (50 grams) was made and showed a lowered tolerance for sugar, the values being as follows: resting blood sugar normal, half an hour after glucose administration 0.18 per cent, one hour later 0.20 per cent, 1½ hours later 0.22 per cent, two hours later 0.135 per cent. A trace of sugar (0.5 per cent approximately) appeared after the second hour.

The patient was put on a full carbohydrate diet and the glycosuria disappeared thereafter.

This case is of particular interest because it illustrates two facts not infrequently found in Graves's disease—namely, that glycosuria made its first appearance with the intensification of hyperthyroid symptoms, following an acute throat infection, and, in the second place, that it disappeared on giving carbohydrates freely.

It is difficult to give a satisfactory explanation of the paradoxical response of thyroid glycosuria to a carbohydrate diet. That the mechanism of thyroid glycosuria is more complex than we imagine is revealed by the very contradictory evidence of the effects of feeding animals with thyroid extract. I have failed to produce glycosuria in four dogs after administering thyroid extract (Burroughs and Wellcome) equivalent to one gram of fresh gland per kilo of body weight daily for over a month. Cramer, Kuriyama,³ and Burn and Marks⁴ have also reported similar failures to produce glycosuria by thyroid feeding. Cramer, however, has observed that experimental hyperthyroidism produced by thyroid feeding leads to a complete disappearance of glycogen from the liver, and Burn and Marks have made the interesting observation that this disappearance of glycogen only occurred at a later stage when thyroid feeding had been continued for some time. These experiments suggest that the action of the thyroid hormone is at first to stimulate the glycogenic function of the liver, and that later one may reach a stage in which this function may become exhausted. If such be the case it is reasonable to suppose that a diet rich in carbohydrates may compensate a defective glycogenic function of the liver, dependent on an excessive thyroid action, by reducing to a minimum the stimulating effect of proteins on the thyroid gland.

A similar explanation may be extended to the effect of a carbohydrate diet on hyperthyroidism generally, thus supporting the view that careful dieting should play an important part in the treatment of exophthalmic goitre, whether surgical or medical, and that carbohydrates should be freely given, as they appear to have a soothing action on the thyroid gland.

Summary

1 Attention is drawn to the importance of careful dietetic treatment in hyperthyroidism, from the following observations: (a) in a study of 69 cases of hyperthyroidism it was found that dyspepsia was both a common and an early symptom in hyperthyroidism, (b) in fractional gastric analyses made on 50 cases of Graves's disease rapid emptying of the stomach and achylia or hypochlorhydria were an almost constant feature.

2 A diet rich in carbohydrates is advocated in the treatment of exophthalmic goitre.

3 Mention is made of the paradoxical response of thyroid glycosuria to carbohydrates.

I have to thank Professor Telling for affording me facilities for carrying out these observations on patients under his care.

JAUNDICE CAUSED BY LARGE EXTRAVASATIONS OF BLOOD

BY

C. E. NEWMAN, M.D. CANTAB., M.R.C.P. LOND.,
MEDICAL REGISTRAR, KING'S COLLEGE HOSPITAL.

IN spite of the general trend of recent work on the pathology of jaundice there are still many who feel that a definite clinical jaundice is impossible without the intervention of the liver. The study of fluids aspirated from haematoma has for some time suggested its possibility, and the two cases I propose to describe seem to put the matter almost beyond question.

Haematoma Fluids

When blood is extravasated into the tissues it is converted into a thick brown mucoid fluid, whose pigments consist of unchanged blood pigments and haematoidin, a substance which has the same composition as bilirubin, and which reacts to van den Bergh's test in the same manner as "delayed reaction" bilirubin. The direct van den Bergh test is often difficult, because the mucoid fluid may be impossible to separate by spinning, but the quantitative estimation is simple, as the alcohol used to precipitate the serum protein carries down the haemoglobin at the same time leaving a clear extract containing the bilirubin. The following table gives the results of the van den Bergh test on several haematoma fluids.

No.	Source of Haematoma	Time since Extravasation	Direct Test	Quant. (Units)	Notes
1	Brulso of thigh	14 days	—	4.0	
2	Breast operation	27 hours	Delayed	2.5	
3	Nostril ecchymosis	9 days	Delayed	12.0	
4	Breast operation	5 days	—	5.0	
5	Breast operation	12 days	Delayed	4.0	
6	Breast operation	2 days	Delayed	2.0	
7	Brulso	3 hours	Delayed	0.2	Unaltered blood
8	Pleural effusion	5 days	Delayed	0.75	Blood introduced by previous aspiration
9	Cyst of breast	3 days	Delayed	3.0	After previous aspiration
10	Traumatic hydrocele	4 months	Delayed	1.2	
11	Haemothorax	20 days	Delayed	4.2	
12	Haematoma ear	6 days	Delayed	4.2	
		5 days later	Delayed	4.5	Had filled up again

None of these patients was jaundiced or passed bile in the urine. The blood bilirubin was estimated in Cases 1, 3, 8, and 12, and was found to be normal. It appears that in between three and twenty-four hours the local reticulo-endothelial cells start to convert the haemoglobin into "delayed reaction" bilirubin, and that thereafter the fluid contains a higher concentration of bilirubin than the circulating blood. It does not seem likely that the liver plays any part in this pigment formation. Many other investigators have already arrived at these conclusions.

Jaundice from Haematoma

CASE I

A male aged 62 had a large hypernephroma removed through a lumbo-dorsal incision on February 10th 1925. The wound was closed without drainage. The anaesthetic used was ether. On February 12th a good deal of bruising was visible round the wound, and on the 14th the conjunctivae were yellow with a great deal of urobilin in the urine, but no bile. Next day the patient was jaundiced all over and there was the most intense local jaundice round the wound. The van den Bergh test on February 16th on the blood gave a delayed reaction (after half an hour) with a quantitative figure of 2.7 units. The levulose tolerance test gave the following result:

Fasting blood sugar	0.103 per cent
50 grams of levulose taken fasting	
Half an hour after	0.122 "
One hour after	0.147 "
One and a half hours after	0.137 "
Two hours after	0.116 "

The bile content of the faeces appeared perfectly normal. The urine contained urobilin but no bile. The fragility of the red blood corpuscles was normal. On February 18th more than a pint of brown slimy blood was aspirated from the wound. This contained 6 units of bilirubin. The jaundice faded rapidly and except for the reactionary temperature during the process of absorption of the remains of the blood the patient made an uninterrupted recovery. There were no symptoms of catarrhal jaundice and the levulose tolerance test was thought to indicate no likelihood of it. There was no past or family history of jaundice.

CASE 2

A female aged 27, unmarried, was admitted to hospital with a large haemoperitoneum on February 23rd, 1927. It probably took place on February 17th, but was not associated with any symptoms except a severe anaemia. The red blood corpuscles, on admission were down to 2,696,000 per cmm. and she was definitely jaundiced with a very slight coloration of the conjunctivae. The van den Bergh test on the blood gave a delayed reaction (in about half an hour) with 3.5 units. There was no bile pigment in the urine, but Hay's test for bile salts was positive on one or two occasions, done in a test tube. Oliver's test was always negative. The levulose tolerance test gave the following result:

Fasting blood sugar	0.096 per cent
50 grams of levulose taken fasting	
Half an hour after	0.111
One hour after	0.120

She was given a blood transfusion and an operation was performed on March 4th, 1927. A sarcoma of the uterus was found which had eroded the uterine artery and had caused a large extravasation of blood through the broad ligament into the peritoneal cavity. The blood was unfortunately not kept so that it was not submitted to the van den Bergh test but it was brown and slimy like other haematoma fluids. There was no past or family history of jaundice and she had none of the constitutional symptoms of catarrhal or toxic jaundice. The jaundice persisted till March 7th.

There seems to be no plausible explanation of these two cases except that the jaundice was caused by the absorption into the blood stream of the "delayed reaction" bilirubin formed locally in rather exceptionally large internal haemorrhages. The positive Hay's test in Case 2 is probably of no significance. I had not then seen Gerard's paper⁴ and have since had abundant evidence of the false positives given by the test tube method.

My thanks are due to Sir John Thomson Walker and Mr. W. Gilhott for their kindness in allowing me to publish these cases to Dr. R. D. Lawrence for the levulose tolerance tests and to Dr. C. R. Lane for the blood fragility curve.

MEDICAL, SURGICAL, OBSTETRICAL

A METHOD OF REPLACING THE RETROVERTED GRAVID UTERUS

THREE years ago Professor Wiener of Vienna demonstrated an interesting method of replacing the retroverted gravid uterus, the value of which I have since been able to prove in my own practice. Although it has many advantages over the methods employed in this country it does not appear to be generally known. It is useful in those cases where manual manipulation fails to replace the uterus.

The patient, lying on her back, has her pelvis tilted up slightly either by a pillow or on an operating table. A stout rubber bag with a capacity of three fluid ounces is passed after being sterilized, into the vagina, behind the cervix. For this purpose a pair of Champetier de Ribes forceps are useful, but not absolutely necessary. Through the tube of the bag is poured slowly a measured quantity of mercury, which, by its weight and diffuse pressure almost immediately raises the fundus past the sacral promontory. Except in the case of an extremely nervous patient the method can be employed without an anaesthetic; indeed an anaesthetic is undesirable in view of the possibility of the uterus being bound down by adhesions. If the mercury is poured in slowly any pain due to adhesions will be reported in time, and the operation can be stopped. The method does not appear to have any ill effect on the uterine contents.

One point of practical importance may be mentioned with regard to the withdrawal of the bag, when the fundus of the uterus can be felt by abdominal palpation. If an attempt is made to withdraw it when full, there is a grave risk of scattering about twenty-five shillings worth of mercury. The pelvis should be lowered, and the patient encouraged to cough or sit up.

This method, in addition to curing the retroversion without delay, and therefore diminishing the risk of abortion, has the advantage of having a strong suggestive effect in the case of a patient suffering from hyperemesis, associated with a retroverted gravid uterus.

MALARIA AND APPENDICITIS

FROM time to time articles have appeared in the *British Medical Journal* on the etiology and diagnosis of appendicitis, but I do not recollect reading any article where malaria has been shown to be confounded with appendicitis, and so I desire to record the following cases which have occurred in my practice during a period of sixteen years.

CASE 1—In 1913 I was called to attend a European woman aged about 40, in Quetta. She had had pain and tenderness in the right iliac region fever and vomiting since the morning and a rapid pulse. There was slight rigidity of the right rectus muscle. The menstrual history was normal. I took a specimen of blood for a rough leucocytosis and found to my surprise benignant tertian malarial parasites present. I gave her an injection of quinine and by the next morning she felt well. I saw this patient about fourteen years afterwards. She had not undergone an operation for appendicitis and so I surmise malaria was the cause of the symptoms.

CASE 2—A European man aged about 26 was sent into hospital at Aden one evening in 1915 for a laparotomy the next morning on account of an acute abdomen. He had been taken ill that morning with abdominal pain fever and vomiting and was told that he had appendicitis or some other acute abdominal lesion. On examination I found pain and tenderness in the right iliac region but the rigidity of the right rectus was not pronounced. This resembled my previous case so I examined his blood and found benignant tertian parasites. I gave him an injection of quinine immediately and next morning he was able to get up and have his breakfast all the symptoms having disappeared.

CASE 3—I was called to see an Indian male aged 19 at Karachi in 1921. The symptoms were similar to the two previous cases, and benignant tertian parasites were found in the blood. He received similar treatment and had quite recovered on the next day.

I have had a few more cases since then, and now make it a rule to examine the blood for malarial parasites.

I wish to point out, however, that the finding of malarial parasites does not negative appendicitis as the following two cases will illustrate.

CASE 1—A European aged 21 at Karachi was admitted for operation with acute abdominal symptoms under the care of the surgeon in charge. An operation revealed a swollen appendix containing mucus. That evening his temperature ran up and an examination of his blood revealed malarial parasites. An injection of quinine made the subsequent progress uneventful.

CASE 2—An Anglo-Indian aged 18 at Kotri in 1923 was under my treatment for malarial cachexia. The spleen was considerably enlarged and malignant tertian parasites were found in the blood. After two months' treatment he regained normal health and the spleen returned to its normal size. Later one morning he reported sick with fever vomiting and pain in the epigastric region and examination of the blood showed malignant tertian parasites. The injection of quinine had no effect. That night the pain became more pronounced in the right iliac region and he was operated upon twenty-four hours later when it was found that he had a suppurating appendix on the point of perforation.

Many authorities have recorded very accurately the symptoms of acute appendicitis and the periods when operation should and should not be undertaken but the surgeon's aim is to operate early within the first twenty-four hours to obtain the best results. It is during this early period that symptoms are apt to mislead, and in the tropics I suggest that malaria should always be excluded. I hope that my cases may interest medical practitioners in the large presidency hospitals in the tropics, and that further investigations may be made.

In malaria the endothelium of the capillaries in the liver is swollen and the parasites are abundant in the capillaries of the villi of the intestine. Does a similar condition occur in the appendix and does it lead to inflammation?

My thanks are due to Dr. Cairns, the chief medical officer, for permission to publish this note.

H. C. DE PENNING, M.R.C.S., L.R.C.P.,
Medical Officer, Kotri District, Sind.

Rebivius.

A FRENCH TREATISE ON CANCER

PROFESSOR MENETRIER's second volume on cancer¹ completes his treatise on that subject. The first volume, which we reviewed in February last year, dealt with generalities, the present volume deals with the forms and varieties of cancer and their treatment. The two volumes, comprising two thousand pages, give an excellent summary of our present knowledge on the subject of malignant disease.

The view has always been held by Professor Menetrier that there is no specific cause of cancer, and he considers that the bearings of modern discoveries and experiments tend to confirm that view, more especially the discovery of a means of producing malignant growths experimentally, enabling their cause and mode of production to be investigated. The causes of cancer, he contends, are multiple and non-specific, physical agents such as x rays, ordinary irritants such as tar, and divers parasites are capable of starting the cancerous process, which is to be regarded as the mode of reaction of the organism against these irritants. He further considers, as the result of his investigation of malignant growths in their earliest stages, that cancer always originates at the site of some pre-existing lesion, apart from which the growth would not arise. Such antecedent lesions are multiple and various in nature, and are grouped by the author under two headings—namely, (1) cellular displacements (heterotopy) caused by irregularities of development, and (2) inflammatory or functional hyperplasias, either simple in character or differentiated into the form of some tumour, such as adenoma or papilloma. According to this view of the origin of cancer it would seem that the line of research demands some shifting of its objective, and should be directed rather towards the elucidation of the chemical, physical, and other effects of ordinary irritation than towards the detection of some definite cause. It might be argued that the extreme frequency with which the tissues of the body are exposed to irritation and the comparative infrequency with which cancer develops at the site of such irritation, renders a causal relation between them improbable. If, however, it is a continuous irritation that is in question, the discrepancy in the frequency of association is probably not so great as might be supposed. The important part played by antecedent lesions has induced Professor Menetrier to devote a large amount of his space to the description of the pre-cancerous conditions mentioned above. Thus a considerable part of the work is occupied with the inflammatory affections and non-malignant growths of the several organs, in the case of cancer of the breast, for example, the various forms of chronic inflammation, cysts, adenomas, and fibro-adenomas, chondromas, osteo-chondromas, and mixed tumours are described in some detail.

Professor Menetrier takes note of the vantage ground which has been gained in recent years through the ability to produce a cancer experimentally, and emphasises the altered views now held as to the curability of cancer. For centuries cancer has been considered to be incurable, we now know that it is not so. Being in its early stages a strictly local affection, excision of the affected tissues will effect as certain a cure as in the removal of a non-malignant growth, moreover, the introduction of modern methods of treatment give some hope that even in somewhat later stages the growth may be completely destroyed. The numerous methods of treatment that are now put in requisition are mostly on their trial, and their proper mode of application is the subject of investigation. Dr H. R. Duval, director of the laboratory of St Michel for the study of cancer, contributes a critical examination of them and their results. Apart from surgical treatment, he speaks in high terms of radiotherapy as applied by those who are conversant with the method. More especially in cancer of the cervix uteri, radiation has given notable results. For example, Regaud's statistics show 26.3 per cent

of cures in inoperable cases, 43.7 per cent in cases at the limit of operability, and 63.6 per cent in operable cases. Meanwhile the practical application of radiotherapy has by no means become more simple in technique, and in incompetent hands it may cause dissemination instead of cure of the disease.

RADIUM IN GYNAECOLOGY

A book on radium in gynaecology is very welcome at a time when this treatment is so much before the medical profession. The subject-matter of Drs Clark and Norris's volume² is well arranged. It opens with a short historical review of the discovery of radium, and in all too brief history of that wonderful scientist Marie Curie. Following this is a very complete chapter on the physics of radium by GIOACCHINO FAILLA of the Memorial Hospital, New York, which at first sight may frighten the ordinary clinician. The necessity, however, of knowing at least the elements of the physics of radium cannot be over-emphasized, and no clinician should start on radiotherapy without such elementary knowledge. This particular chapter is extremely well written, and the book should be read if only for that reason. The next section is somewhat quaintly headed "The pathology and action of radium." The action of radium is still a matter which requires a great deal of investigation, but the general trend of recent work is well summed up.

It is the second half of the book which really deals with the clinical uses of radium in gynaecology, and tumours of the external genitalia are the first to be dealt with. The authors are not satisfied with merely dealing with the methods of treatment by radium and their results, but go, in considerable detail, into such matters as diagnosis and etiology of the disease. They advocate radical surgical excision where possible, with removal of glands, implantation of radium emanation, followed by x rays as soon as healing is complete. Unfortunately they do not give any figures as to the results of such treatment compared with excision alone. In describing the technique they do not mention whether their "seeds" are purely glass or encased in thin platinum. They also make use of that very indefinite measurement millicurie hours. To give one example, they say that the inguinal region is treated for 3,000 millicurie hours at 4 cm with lead blocks. At the end of this paragraph it is stated that excellent results were obtained by this method, but no figures as to the length of time the patient survived or other details are given. The next chapter deals with tumours of the vagina. The authors raise an interesting point concerning the production of fistulae, and quite rightly remark how often this complication is due to the disease and not to the radium, as is sometimes suggested. The chapter on carcinoma of the cervix is somewhat disappointing, especially for the way in which the statistics of the authors' own cases are dealt with. Even after reading through this chapter it is difficult to get any clear idea of how long the patients lived and to what extent they were relieved of their various symptoms when treated by radium alone. A few tables in this connexion would show at once what the results were. The word "cure" appears fairly frequently, and it can only be surmised that three years without symptoms or signs of disease is meant. Clark and Ferguson are quoted as saying that irradiation alone cured 28.5 per cent of Stage I cases, but irradiation combined with cauterization and trachelectomy cured 83 per cent. This certainly suggests that in their hands a trachelectomy has more to do with the "cure" than the irradiation.

In their discussion of technique the authors state that in Stage I operation is justifiable, but in their opinion radium is better. It appears that in these cases they combine the radium treatment with a trachelectomy, but how much radium is used and how long they use it for are difficult to gather. In Stage II they follow much the same procedure, except that they do not always perform trachelectomy. In Stage III cases are treated by a single dose of 2,500 milligram hours (by a printer's error this appears as milligrams). Stage IV cases—that is, the very advanced—

¹ *Nouveau Traité de Médecine et de Thérapeutique*. Publié sous la direction de J. P. Carrot et P. Lereboullet, XIII bis. Cancer. Formes et Variétés des Cancers et leur Traitement. Par P. Menetrier. Deuxième édition revue et considérablement augmentée. Paris: J. B. Baillière et Fils (Roy Bro pp vi + 433-2000 344 figures, 120 fr.)

² *Radium in Gynecology*. By John G. Clark M.D. and Charles G. Norris M.D. With a chapter on Physics by Gioacchino Failla E.E. D.S.C. London: J. B. Lippincott 1928 (Med Bro pp vii + 315 49 figures, 5s net.)

should not, in the opinion of the authors, be treated by irradiation. In discussing on page 199 the action of radium Drs Clark and Norris state dogmatically that this is produced in three ways—namely, by autolytic degeneration (particularly noticed when applied to the unique type of tumour), by caustic action, and finally by growth restraint. Most people will find it difficult to be so certain about the action of radium. The next chapter, on encephaloma of the body of the uterus, deals more with surgical than with radiological treatment. Here, again, we are told that 5,000 to 7,000 milligram hours is none too much, but are not told for what number of hours the treatment is given. The rest of the book deals with non-malignant conditions, such as fibroids.

DEVELOPMENT OF THE HUMAN EYE

THERE is no type of book which repays the reader with more pleasure and stimulation than the monograph wherein a writer who has laboured long over a subject gives to the world his results and deductions, and in the light of the new knowledge recasts his subject, sometimes in essentials, sometimes in minutiae, to conform with his conceptions. If he is right in his main contentions a landmark may have been reached, if he is wrong the interest is but little lessened, for he has usually succeeded in imbuing the facts of science with some of the clothing of personality and giving them an interest richer than they had before. Ophthalmological embryology in this country owes a debt of this kind to Miss Mann. Until a few years ago this subject was to all intents and purposes neglected, and its elucidation was left to Continental investigators, she has saved English ophthalmology from a reproach, and has given this branch of the specialty a vitality of its own with results that speak for themselves. With the help of Professor FRASER of the University of London she has accumulated the largest selection of human embryos at different stages of development that has yet been gathered in this country, and these she has studied in detail, at the same time correlating her findings with those of others. From her own observations she has been able to build up a connected story of the development of the eye most of it was known before and is merely recapitulatory but she has filled in several important blanks, and she has been able to express a reasoned opinion on several debatable points. With her opinion everyone may not agree—if they did embryology would lose much of the interest which it appears destined to claim for a long time to come, whether they do or not is immaterial but there will be few who will deny that she has attained the position of one whose opinions on this particular subject with which she has identified herself demand respect and consideration.

The *Development of the Human Eye*² opens with a chapter on the early stages of the formation of the primordially optic vesicle, the development of the embryonic plate, its lateral out-pouchings to form the optic pits, and its differentiation to form the optic vesicle. There follows a description of the development of the neural and surface ectoderm and the mesoderm which is associated with it until the fully differentiated eye at birth is reached. Incidentally the rationale of several congenital deformities is explained, such as microphthalmia, congenital cystic eyeball, anophthalmia, colobomata. The development of the lens is then dealt with, in which connexion reference is made to the subject of congenital cataract. The fourth chapter deals at great length and in considerable detail with the differentiation of the neural ectoderm into the different layers of the retina and the prolongation of this structure over the ciliary body and iris, it includes a description of the sphincter and dilator of the pupil, and an account of the development of the optic nerve and chiasmal region. The next chapter, dealing with the vitreous is one of the most interesting for over the development of this tissue disputations have taken place since the middle of last century. The author's suggested solution of the problem is that the vitreous has a triple origin, partly from the lens plate, partly from the optic vesicle, and partly from the mesoderm which enters the

optic vesicle through the foetal fissure. Under the heading of "the associated mesoderm" the next chapter deals with the foetal blood system—the larger vessels in the orbit, the development of the choroid, the development and the retrogression of the foetal intraocular blood system, and the development of the definitive retinal arteries and veins—the mesodermal portion of the iris and ciliary body, and the development of the corneo and sclerotic. The differentiation of the structures of the orbit and its contents is then detailed, and the book finishes with a comparative study of phylogenetic and morphological points of interest. There is appended a comparison, in synopsis, between ocular and general development and, finally, a comprehensive bibliography.

In the preface Miss Mann hints that the book will have a limited interest. If it does it will be unfortunate. To the embryologist, the anatomist, the zoologist, and the biologist it should be a necessity, to the ophthalmologist it should be more than a luxury. A certain amount of embryological knowledge is needed if clinical findings in the eye are to be rightly interpreted, for the explanation of many ocular appearances is embryological moreover upon the differential diagnosis of congenital from acquired conditions many decisions of importance rest and this can only be adequately appreciated in the light of a knowledge of the normal and abnormal development. In this connexion it should be noted that the *British Journal of Ophthalmology* has undertaken the financial responsibility for Miss Mann's book. The volume is lavishly and beautifully illustrated with drawings executed by the author and can have been produced only at considerable cost. It is well for British ophthalmology that work of scientific value and international significance should be sponsored and facilitated in this manner by its official organ.

BLOOD TRANSFUSION

La transfusion du sang de l'animal à l'homme,⁴ by Professor RENE CRUCHET of Bordeaux and his assistants, Dr. A. RIOT and CAUSSEMON, deals with a subject on which the professor's name is well known, for at the Nottingham Meeting of the British Medical Association in 1926 he covered much the same ground, though naturally in less space and with fewer illustrations. In his introduction Professor Cruchet tells the reader the story of the difficulties and opposition he had to overcome in carrying out his animal experiments on transfusion. The historical summary shows that, although the idea of transfusion is almost as old as history, it was not put on a sound logical basis until Harvey's discovery of the circulation was published in 1628. The true story of the opposition to Jern Denry's transfusion of man by sheep or calf's blood in 1667 and the long period of its neglect shows that it was due to the Medical Faculty of Paris, which enacted that transfusion could not be done without the approval of a member of the Faculty. Denry, it is significantly pointed out was a professor of mathematics and philosophy at Montpellier and not a medical man. Attention is directed to the work of Oré of Bordeaux, who between 1860 and 1876 advocated human transfusion with animals' blood, and ascribed the untoward effects sometimes seen to coagulation and embolism. These conclusions are confirmed and expanded by Cruchet and his colleagues as the result of numerous experiments. They advocate heterogeneous transfusion as free from disadvantages, such as want of control of the human donor, and as possessing the obvious assets that an animal can be immunized against a number of infections and that the therapeutic results are better than those obtained by transfusion of one human being with the blood of another. The precautions to be taken in transfusion are set out, the causation of serious reactions is fully considered, and the conclusion is reached that agglutination and haemolysis are harmless, provided that the proper technique of transfusion is followed, the most important point being, that the procedure should be carried out very slowly, especially in transfusion from animals to man, a method which the authors consider is then free from danger.

² *The Development of the Human Eye*. By Miss C. Mann M.B. B.S. Lond. I.R.C.S. Eng. With a foreword by Sir John Herbert Parsons C.B.E. D.Sc. M.B. I.R.C.S. F.R.S. London: Cambridge University Press, 1928. (Pp. 8vo pp. x + 206. 24 figures. 36s. net.)

⁴ *La transfusion du sang de l'animal à l'homme*. Par René Cruchet, A. Riot et J. Caussemon. Collection Médecine et Chirurgie pratiques. Paris: Masson et Cie, 1928. (5 x 7 1/2 pp. 103. 13 figures. 12 fr. sans majoration.)

PATHOLOGY

THE revision for the fourteenth edition of DELAFIELD and PRUDEN'S *Text-Book of Pathology*¹ has been carried out by Dr F CARTER WOOD. The general features of the book remain unaltered, but additional matter has been included on the subject of vitamins and hormones, changes have been made in the chapters on diseases of the thyroid, pancreas, lungs, and blood, and modifications in our conception of certain lesions of the liver and gall bladder have been referred to. Additional matter has also been inserted in the chapter on infectious diseases, in that dealing with the bones and joints, and in that on the nervous system. The chapter on lesions following various types of poisoning has been eliminated, as these matters are considered to be covered more fully and satisfactorily in the standard works on legal medicine. The description of the technique of *post-mortem* examinations has been curtailed in order to make room for more important matters. As a textbook for the student of pathology the work remains one of the soundest and most reliable among the numerous works of the kind at his disposal. It presupposes a fair knowledge of gross and microscopic anatomy, embryology, biological chemistry, and physiology on the part of the student, and starting on this basis furnishes him with the fundamental facts of pathology, fully yet tersely described, with a clear discrimination between fact and theory, but with an adequate discussion of the latter in all problems of importance. Dealing with so large and rapidly expanding a subject a work of this kind, notwithstanding its considerable size, necessarily gives to some extent an epitomized presentation, but in connexion with the description of almost every lesion useful and well chosen bibliographical references are given to guide the student who seeks for more detailed information.

GUY'S HOSPITAL REPORTS

ALTHOUGH there is not any contribution in the April instalment of the *Guy's Hospital Reports*² actually under the editor's name, his influence is obvious, especially in the first four articles dealing with various gastric conditions, the first two of which are based on the material from the New Lodge Clinic since its opening in February, 1921. Dr L J BARFORD's statistical inquiry into the etiology, symptoms, signs, and results of treatment in 166 cases of gastric and duodenal ulcer is a very valuable analysis and, the diagnosis being based on clinico-chemical and particularly on radiological data, differs from most previous collections which have been the result of observations made at operations or *post-mortem* examinations. Among the 160 chronic cases, 128 were duodenal, 30 gastric, and 4 ulcers in both regions. This article is followed by Mr T EVANS Jones's analysis of 55 cases of unsuccessful gastro-jejunostomy, of which 36 were diagnosed as jejunal or gastro-jejunal ulcers, 4 as persistent or recurrent gastric or duodenal ulcers, and 15 as other bad results or complications. Dr R C BLOCK's article on four cases of gastro-colic fistula contains a useful commentary on the subject, which shows that malignant disease of the colon, formerly almost the sole cause, has now become rare, and that most of the cases are due to jejunal ulcer following gastro-jejunostomy for duodenal ulcer, all except one of these fistulae being in males. In an investigation, undertaken at the suggestion of Dr HURST, into the relative efficiencies of the commoner substances, collectively known as "alkalis," in the neutralization of free hydrochloric acid in the gastric juice, Messrs C R E FREEZER, C S GIBSON, and E MATTHEWS find that tribasic magnesium phosphate is the most suitable for the rapid correction of gastric acidity, although tribasic calcium phosphate, the citrates, and calcium carbonate are almost as good, that

magnesium oxide and carbonate are rapid neutralizing agents, but that they both produce a hydrogen ion concentration far from the optimum for the tissue cell, and further, that after their administration alkalemia is liable to occur, and that of the substances examined, bismuth oxy-carbonate is the least effective for the neutralization of gastric hydrochloric acid. Jaundice of the newly born, with special reference to physiological jaundice and grave familial jaundice, is described by Dr A C HAMPSHIRE, who has made a number of observations on the blood. Dr BAND records a case of typhoid fever in which a relapse occurred seventy-five days after the original attack. Mr GIBBERD communicates a case of epistaxis and haematome of the vulva associated with the albuminuria of pregnancy, and Dr C P BLACKER discusses at length the dreams of a patient as an index of his inner life. In conclusion, it may be pointed out that these Reports always contain papers of special value which are not published elsewhere.

NOTES ON BOOKS

Dr ROBERT HUTCHINSON, in the preface to his reprint of three addresses, *Some Principles of Diagnosis, Prognosis, and Treatment: A Trilogy*,³ admits that there is nothing in them that has not been said often before, but the critic, however candid he may wish to be, must admit that there can seldom have been more interesting and shrewdly worded advice than that closely packed in these fifty-four pages. The first address, on diagnosis, appeared originally in our issue of March 3rd, 1928 (p. 335). While thoroughly practical and full of common sense, wisely diluted with humour, there are many epigrams which the medical man would do well not only to read but to remember, and there can be no doubt that mental physics so pleasantly flavoured will have much more lasting effect than the formal dogmatism of the dry dust type of textbook. It is easy reading, but this is the artful product of long clinical experience, an extensive acquaintance with good literature, and much successful writing.

Culture the Diffusion Controversy,⁴ a volume in the General Series of the *Psyche Miniatures*, contains four short essays. In the first of these Professor G ELLIOT SMITH states the two views of the origin of civilization, the first, held by the vast majority of anthropologists at the present time, is that civilization has grown up in various communities quite independently of similar events taking place elsewhere in the world, the other, which he strongly supports by many instances, is that civilization, like any invention of which we have knowledge, has spread from one centre. Professor MALINOWSKI in the next twenty pages vigorously controverts Professor Elliot Smith's arguments, and sums up to the effect that diffusion never takes place: culture is a readeption, a truly creative process in which external influence is remodelled by active genius. In the longest of these essays, The prehistoric versus the romantic (diffusionist) school in anthropology, Dr SPINDER brings in the analogy of parasitic diseases, which he considers are most unlikely to arise spontaneously in different areas, and expresses doubt whether any parasitic disease of importance was common to the New and Old Worlds at the time of the discovery of America and its colonization by Europeans: he apparently has no hesitation in accepting the view that syphilis spread from America to the rest of the world. He, however, concludes in somewhat scornful terms against the romantic school. Dr GOLDENWEISER also criticizes Professor Elliot Smith's contention, and in the main agrees with Dr Malinowski but he is not inclined to deny dogmatically the influence of diffusion.

Drs E M BROCKBANK and A RAMSBOTTOM's compact little handbook on *The Clinical Examination of the Lungs*,⁵ which was reviewed in our columns seven years ago, when it first appeared, has now passed into a second edition. It has been slightly enlarged, has some new diagrams, and four plates, each containing two skiagrams, of the normal and morbid appearances of the chest. It is admirably adapted for students when commencing work in the medical wards and out-patient departments.

⁵ *Guy's Hospital Reports* Vol. 78 (Vol. 8 Fourth Series) No. 2 April, 1928. Edited by Arthur F. Hurst, M.D. London: The Lancet Limited. 1928. (6 x 9 1/2 pp. 127-252. 3 plates. 16 figures. Annual subscription for volume of four parts £2 2s. or 12s. 6d. net per issue.)

The American Medical Association of Vienna, which was founded in 1903 to promote post-graduate medical work in that city, was reorganized in 1921 and at the beginning of 1927, adopted as its official organ *Iris Medica*, an English edition of which had existed for five years previously. The journal is published monthly and includes abstracts of current German medical literature, answers to clinical and scientific questions arising in practice, notes on drugs and official information about the association. The bound volume for 1927 represents a well arranged and useful summary of German medical literature during the year, together with an index of subjects and of authors.

The application of science to everyday life involves the disappearance of empiricism even from the art of cooking. Thus we find a physiologist Professor MORTIMER, associated with Miss JESSIE LINDSAY, head of the household arts department of King's College for Women in the production of a *Manual of Modern Cookery*. Cook can now learn the respective amounts of proteins, fats, carbohydrates, salts and vitamins she should allow to the family for which she enters and, if kept properly informed, she will cure the constipation of the household with a due administration of roughage. Miss Lindsay discusses on the various methods of cooking food and the reasons for adopting different methods for different joints. Her 854 recipes include every variety of dish, and though the book is perhaps more suitable for schools and colleges than for the ordinary domestic servant, many of the recipes are well within the competence of the good plain cook.

Manual of Modern Cookery. By Jessie Lindsay and J. H. Mortimer. London: University of London Press Ltd. (5s. x 8, pp. 316, 48, 6d.)

PREPARATIONS AND APPLIANCES

NON FLAM EYE SHIELDS

The dangers of using ordinary celluloid for articles that may be brought near fire is very great and there have been noted in the columns of the *Journal* not a few incidents that provide a warning against the use of this material. It might be thought that eye shields were unlikely to be a danger in this respect, but the recent experience of a patient who was severely burned about the face through wearing a celluloid eye shield proves the contrary. While he was lighting a cigarette a wisp of cotton wool projecting from beneath the shield caught fire, this in turn fired the shield, with the result that a grave burn was sustained. Common celluloid can usually be recognized by its slight smell of camphor, non-flam has no smell. Messrs Solport Brothers Ltd. of 184 Goswell Road, E.C.1, have now produced appliances which, though very like the former celluloid shields in appearance, are non-inflammable. They are sold under the trade name of

Portia shields and are marketed in the usual opaque form of single eye shields and also as tinted transparent shades for protecting the eyes from excessive sun or artificial light. If one is rash enough to throw an ordinary celluloid shield into the fire there is an instant burst of flame of almost explosive force. When one of these non-flam shields is put into a bright fire it gradually curls up, and then half smoulders half burns away leaving an appreciable residue. There is no doubt about the safety of this new material: it burns with reluctance even in the heart of the fire. One point however might well receive attention from the makers. These eye shields have no provision for ventilation: there should be a series of small perforations parallel with the upper border and at a sufficient distance from it to allow free access of air when the appliance is fitted to the face. Water-proof shields fit so well that unless ventilated they are worse than useless: they act as incubators and are definitely injurious to the eye. With the ventilation suggested these Portia non-flam shields will be a useful surgical appliance.

SIXUS FORCEPS FOR BURYING THE APPENDIX STUMP

Mr HUGH DOXOVAN, FRCS (Birmingham) writes: In the common method of burying the appendix stump after appendicectomy by thrusting it with forceps into a purse-string surrounded area it is a not unusual experience to find the forceps held by the purse-string on withdrawal. Messrs Thackray of Leeds have made for me a modification of Hilton's sixus forceps, the blades being perfectly plain without any serrations and being free from the slightest trace of a bulbous end. These forceps have proved satisfactory in practice.

ROYAL MEDICAL BENEVOLENT FUND

THE FUND is endeavouring to help the widows of medical men who in many cases are living in penury, to assist orphans who are faced with hunger, and to support broken and infirm medical men who in the last days of their life are in need. An urgent appeal is made for subscriptions and donations, as funds are very greatly needed to continue this work of kindness. Cheques should be sent to the Honorary Treasurer, Sir Charles Symonds, 11 Chancery Street, Cavendish Square, W.1. At the last meeting of the committee 47 applications for

assistance were considered, and grants amounting to £792 were voted, making the total sum of £5536 in grants this year. This sum is considerably larger than the amount voted during the corresponding period of last year, thereby showing that increased demands are being made upon the Fund.

Of the many applications considered, the following short notes on two of the cases are typical, and show how distressing are the stories which are told.

Mrs. A. aged 72. Her husband died this year at the age of 92. He had held a post as medical officer of health and had to retire in 1919. Although the post carried no pension he was granted £50 a year under the complimentary title of consulting medical officer. For nine years of retirement this old couple lived on £350 a year. On the husband's death this payment ceased and the widow was left without a penny. Of her three sons the eldest suffers from a war disability and is only able to earn £55 but contributes £25 towards his mother's maintenance. The second son was badly hit in the war and is now a clerk in Canada and cannot help the youngest in farming in the colonies. He is married and has his own family to keep. The Fund voted £36 in four instalments.

Mrs. Y. whose husband was killed in an accident was left with four boys. The practice was sold and with the proceeds thereof the widow tried to run a boarding house, which failed. Realizing what she could not do of this failure she rented a house and took in lodgers when a devastating and unexpected blow fell upon her. Her husband had been given a loan by a friend which had always been looked upon more as a gift than as a loan. The friend had also undertaken to pay for the education of one of the boys. The friend died recently and the executors insisted on the repayment of the loan. The widow offered a cash payment of half the sum but this was refused. There followed a foreclosure and the seizure of all the furniture in the lodging house and the loss to the widow of her last means of livelihood. The Fund voted £40. With this timely help and by the generous action of the local Panel Committee the widow has been enabled to restart.

Subscriptions to help cases such as these are asked for.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58 Great Marlborough Street, W.1.

NEW ZEALAND HOSPITALS

A SURVEY OF THE SYSTEM

THE Department of Public Health of New Zealand has recently issued, as an appendix to its annual report, a voluminous survey of the hospital system of the Dominion. This should prove of interest to British readers for they will find in its pages an account of the changes through which a spontaneous and sporadic charitable provision of hospitals has become a more or less systematized organization. The hospitals and charitable aid system of New Zealand has recently been the subject of considerable comment, due in large measure to the increase in hospital expenditure, and the aim of the report has been to give the record of an unbiased examination of the whole position.

Some of the hospitals of New Zealand are maintained entirely by the Government, most receive subsidies equal in amount to their voluntary subscriptions and local levies, a few receive higher payments. By an Act of Parliament of 1909 a hospital and charitable aid board was set up for each district. A primary defect now seen in this arrangement is that the hospital districts are not large enough to be self-contained—that is, to maintain a base hospital, infectious disease and maternity hospitals, secondary or cottage hospitals, an old people's home, district nurses, and subsidized medical men in outlying areas. Many districts have no base hospitals or special hospitals: their cases therefore go elsewhere, and there is constant friction over costs. Further the multiplicity of boards tends to make administration costly. amalgamations have been attempted, but local prejudices are too strong to permit them and the tendency has been for outlying districts to claim independence in the hope of lightening costs. The boards are elected bodies, representation being proportional to a mean between the population and the value of the rateable property in the contributory areas. This again gives rise to disputes between town and country, for the townsmen favour the parliamentary franchise. The Government provides most of the money but is practically unrepresented on the boards, for,

¹ Department of Public Health. Appendix to the Annual Report for the year ended March 31st 1927. Containing a Survey of the New Zealand Hospital System. December 1927. Wellington. W. A. G. Skinner Government Printer 1928.

while the Director-General of Public Health may attend, he manifestly cannot be present at all meetings. It is argued that it would be good if there were a Government representative present, if only as a liaison officer. "With a view to reducing rhetoric, all the more important boards form committees", these do the work, and the boards any co-opt outsiders to them.

Work of the Hospital Boards

An improvement in personnel is noted. "There is not a great deal of kudos in hospital board work, and men merely seeking personal advancement in public life do not as a rule use the hospital boards as a stepping stone thereto." But the work is of enthralling interest, and "we find men giving up other public work and devoting themselves entirely to hospital board activities." The chairman may receive an honorarium of from £100 to £250 per annum, according to the scale of revenue, and members may receive travelling and sustenance expenses. The Board of Health for the Dominion is stated to be a thoroughly representative body, and we note that it contains a representative of the British Medical Association. Local boards are permitted to appoint representatives of the honorary medical staffs to their membership. There are the usual finance and house committees, and recently 'fees committees' have been formed, the reason being that "the growing cost of hospitals, and the tendency to extend their advantages to all classes of the community, makes it desirable that boards should give more attention to the matter of the collection of fees." There is a paragraph describing the internal administration of the hospitals, and the relationship of medical superintendent, managing secretary, and matron. "The medical superintendent is the recognized head of the institution," yet the others are in charge of their own departments and responsible, therefore, to the board.

It will have been noted that the boards are not hospital authorities only, they are also charitable and authorities and provide for the destitute. The report quotes a long paragraph from Mr Sidney Webb's book *The Prevention of Destitution* on the development of modern Poor Law methods, as showing the superiority of prevention of destitution over casual charity. New Zealand authorities, the report says, have done little in this direction, they merely give such relief as is necessary and sufficient. It is urged that "each board should be a charitable organization society for its own district," co-ordinating existing charities, which can do things that the ratepayers' boards cannot do. The report is strongly opposed to the suggestion that charitable aid should be separated from hospital administration and that it should be undertaken by the State, on the ground that relief would cost more, and that "some of the most enlightened methods of relief could hardly flourish except under a voluntary system." The care of orphan children comes within the scope of the welfare branch of the Education Department.

Financial Organization

The district boards are financed from four sources: patients' payments, voluntary gifts, levies through the local rates, and State grants or subsidies. The State gives £1 for every £1 collected through gifts or through the levies on the rates, and it is therefore to the ratepayers' interest that the voluntary gifts should be as high as possible. But it appears that voluntary contributions have not increased by reason of this stimulus. "It having been decided that the care of the sick is a national affair, and not one to be left to haphazard charity, the public no doubt consider that, having paid their hospital rates, there is no need to supplement such payments by voluntary contributions. Many boards have abandoned the idea of collecting voluntary contributions at all, and will not undertake a hospital Saturday, holding that, as hospital finance is assured, a clear field in this respect should be left to other charities who are dependent solely on voluntary contributions." The proportions obtained from the main sources for last year were as follows: patients' payments, 20 per cent, voluntary contributions, 13 per cent, local levies, 29.2 per cent, State grants, 36.6 per cent.

Private Wards

The suggestion that there should be wards for paying patients is strongly opposed by some on the ground that it will promote class distinctions. In many country districts there is no such demand, for all are content to avail themselves of the existing service.

"The opinion of many business men with considerable hospital experience is that it would be a difficult task to make private wards pay at the fees usually charged by private hospitals. Apparently it would cost at least £8 8s a week to cover the full cost including all overhead charges in view of the eight hours system for nurses and other factors to be taken into consideration, and this is only if the wards were constantly full and there were no bad debts. Even a hospital designed for paying patients by such a skilled administrator as Henry Ford does not appear to be able to pay its way at less than the above rates."

Payment of Medical Staff

The medical staff do not receive any financial recognition of their services, but

The Director-General has definitely expressed his opinion that the time has come for the abolition of the honorary staff and that, as hospitals are open to all it is not right to expect the services of the medical profession in an honorary capacity. It is difficult to see from a financial aspect at any rate what other conclusion could be come to. The honorary system is only suitable for hospitals treating only pauper patients, and it could not be expected that the medical profession should give their services free unless some *quid pro quo* in the form of a voice in regard to hospital policy and administration were given them. The engagement, however of any other class of employee upon such an understanding would be absurd and unbusinesslike and it seems just as unbusinesslike in the case of the medical staff.

The views of the New Zealand Branch of the British Medical Association are then put in *extenso*, these correspond closely with the hospital policy of the British Medical Association at home, but with certain special stipulations. The report sums up the effect of the local British Medical Association policy thus:

"The British Medical Association appear to favour the 'open hospital' system—that is, that they apparently are prepared to continue to give their services free in the public wards provided the boards will erect private wards in which they can treat their private patients. The tendency of the hospital boards seems to be opposed to such suggestion and they appear generally to favour the 'closed' hospital—that is, a hospital on which the medical staff is stipendiary."

General Conclusions

It appears from this report that the hospital system in New Zealand is unique.

"Through the length and breadth of the Dominion hospitals are available for all who seek admission. The necessary money for the upkeep of these hospitals is fully assured and is not dependent upon sentimental appeals. These institutions are owned by the people administered by the people and paid for by the people. One of the main principles of our system is that of local autonomy, the administration being in the people themselves by means of boards elected by the people of the district in which the hospital is situated. There is indeed a measure rather of supervision than control vested in the department but the department is not represented on the hospital boards and does not desire to be represented."

The second part of the report deals in detail with the several departments of hospital administration—costs, accounting, and so forth. There is evidently a definite struggle in progress between the advocates of payment by patients and free hospital service. At present patients who can do so pay 9s a day, an attempt to raise the normal charge to 15s in 1925 failed. Others assert that their payment of rates provides the service for them when they need it, like the payment of fire insurance. Friendly societies pay the dues required of their members and their families, but demand a 50 per cent reduction in the charge in return for their guarantee of payment, this the report declares to be unconscionable, as the charge made falls far short of the cost. Reference to this question was made in the *British Medical Journal* of March 31st (p. 563). Attempts have been made to develop State-subsidized industrial contribution schemes as an insurance against hospital benefit.

The answer to criticisms of the high cost of the hospital service is given tersely thus:

"Decrease in the purchasing power of the £1 note, increased number of hospital beds, increase in staff required owing to the more complicated methods of hospital treatment including the employment of a greater proportion of trained nurses and the institution of employees' superannuation."

NATIONAL CONFERENCE ON MATERNITY AND CHILD WELFARE

A CONFERENCE under the auspices of the National Association for the Prevention of Infant Mortality, and presided over by Sir GEORGE NEWMAN, was held at the London Guildhall on July 5th and 6th. It was largely attended by representatives of medical and social welfare organizations and of local authorities. In his address from the chair Sir George Newman said that he doubted whether anyone could point to a voluntary movement which had been taken up so readily, pursued so persistently, and had yielded its results so promptly as that for the saving of child life. He described the fall in the infant death rate during the last thirty years as the result of many factors, but of one above all, namely, the awakening of interest in maternal care on the part of the community. He indicated four lines of further advance: steady continuance of the attack upon preventable mortality, concentration on, and a fuller understanding of, the social causes of mortality and sickness, the development and extension of the care of children of pre-school age, and, finally, an increase of solitude for the mother. When a woman died in performing the greatest of all physiological functions there should be an adequate inquiry into the cause.

Maternal Mortality and Morbidity

A discussion on the causes and prevention of maternal mortality was opened by Mr. Eardley Holland, who said that childbirth ranked third as a "killing condition" among women of child-bearing age, it was exceeded by tuberculosis and organic disease of the heart. The principal mortality rate had fallen only by a fraction since the early years of the century, a humiliating state of affairs, having in view the improvement which had taken place in general health. Five countries had an appreciably lower mortality than our own—namely, Holland, Denmark, Sweden, Norway, and Italy—the figures ranging from 2.3 to 2.8 per 1,000, as compared with the British figure of rather over 4. By a comprehensive and well-directed effort we might place ourselves on a level with the Scandinavian countries, thus halving our maternal mortality rate, saving the lives of 1,500 mothers a year, and improving the health of an infinitely larger number. It was a significant fact that the Swedish maternal mortality rate had not fallen during the last twenty-five years, and it appeared as though a mortality rate of about 2.5 per 1,000 was the irreducible minimum. Mr. Holland went on to describe the conditions in Sweden, from which he had lately returned. Medical students there, during four months of their curriculum, lived and worked in the maternity hospital. The period of training for midwives was two years, and the training was uniform, being conducted in the big maternity hospitals, and not in a large number of minor training centres as was the case in Great Britain. Midwives in Sweden were educated women, many of them of a high social class. No woman in Sweden, not even the highest lady in the land, was attended at her confinement by a medical practitioner unless there were complications. Even when the doctor administered the anaesthetic, the labour was left entirely to the midwife. Of all the confinements in Sweden 30 per cent took place in maternity hospitals. Among the differences which Mr. Holland had noted as between the Scandinavian and the British outlook was that the British woman regarded approaching childbirth with fear—indeed, the impression of fear was sown in her heart as a girl when she attended church and heard the prayer for "women in travail, sick persons, and young children"—and he believed that fear affected the function of the uterus and accounted for many painful and lingering labours. In Scandinavian countries, on the other hand, childbirth was regarded as a perfectly natural and even domestic function, largely because of the complete confidence in the obstetric services.

Dr. VIVIAN CLARK (M.O.H., Manchester) said that there was likely to be a diminution in the number of those

delayed and difficult labours which occurred as a result of deformities of the pelvis. The great cause of bone deformity was rickets, and from various sources, including school medical examinations, there was evidence that rickets was a disease which the public health administration in this country was eliminating. Dr. Clark pleaded for a subsidized midwifery service. Mr. ALECK BOURNE said that while watching the work of some nurses he had been convinced that the true principles of asepsis had never been learned. Too much antiseptic was sought—in other words, reliance on disinfectants to kill organisms on the hands and appliances—and there was not enough emphasis on cleanliness by washing. The killing power of chemical preparations was perhaps emphasized too much in teaching and so an excess of confidence in these substances was created. Even the rubber glove was dangerous if the nurse used it in touching objects other than the patient's genital passages, but he had known nurses who seemed to think that the rubber glove *per se* gave complete protection.

A discussion on maternal morbidity, which in some ways overlapped the discussion just reported, was opened by Dr. BECKWITH WHITEHOUSE, who set out certain essential factors in the attainment of a low morbidity rate—namely, that the trained nurse-midwife should be recognized as the most suitable attendant for all normal obstetric cases; that ante-natal supervision ought to be considered as the duty of the medical profession, that ante-natal centres should be set up in all areas, at which medical practitioners might attend and see their own patients as well as those submitted by midwives in the area, that these centres should provide at public cost sterilized obstetric outfits, that panels of obstetric specialists or consultants should be instituted to provide expert opinion if required by a medical practitioner, and that in-patient maternity departments might be made available in all hospitals and infirmaries for the investigation of difficult ante-natal problems. Mr. FRANK COOK (assistant obstetrical surgeon to Guy's Hospital) dealt with the maternal morbidity due to miscarriages and abortions, which he was inclined to think that women as a whole regarded far too lightly, and Professor LOUIS McILROY and Miss ESTHER RICHARDS discussed the advantages of post-natal clinics, the former describing the system which had been practised for four years with excellent results in the obstetric department of the Royal Free Hospital, and which served to link together the obstetric and infant welfare departments.

Reduction of Infant Mortality

Yet another discussion was on the value of intensive methods in the reduction of infant mortality. Dr. ERIC PURCHARD gave an account of some investigations into the neo-natal death rate of certain boroughs. The very general decrease in this death rate recorded in recent years was not attributed by those concerned to any one factor but to a combination of factors, mostly connected with the improved organization of child welfare administration, the greater number and efficiency of health visitors, better housing, and the more satisfactory midwifery service. Dr. S. G. MOORE (M.O.H., Huddersfield) gave an account of the intensive methods adopted in his area, whereby the infant mortality figures in a special district fell from 111 in 1912-14 to just below 70. Dr. HAMILTON WOOD also described certain results in Warwickshire in the same direction, pointing to the value of voluntary effort and co-operation in a rural community. Sir FREDERICK TRUBY KING told the now familiar story of the child welfare movement in New Zealand of which he is the director.

Finally, a discussion was held on the particular problem of the unmarried mother and her child, in the course of which Dr. R. A. LISTER (M.O.H., Hampshire), after mentioning that the mortality rate for illegitimate infants was almost double the general rate, dealt with the social handicaps placed upon the illegitimate child and its mother. He contended that the unmarried mother did not receive fair play. Her condition was certainly better than it was ten years ago but among religious bodies and some social workers much prejudice still remained. The position of the unmarried mother in England was rather worse than in many other countries, though better than in certain of the American States. Years ago it was quite common

for district nursing associations to make it an unbreakable rule that the district nurse should not be allowed to attend the unmarried mother, and although, through the active help of the Ministry of Health, this rule had been broken down, such concessions as were made were in a grudging spirit, and enormous pressure had to be exercised to secure the entry of these unmarried mothers into institutions. Dr. Lyster contended that such segregation was entirely bad as a general principle, and that a strong effort ought to be made to keep mother and child together in domestic surroundings, the institution being the last resort.

The Guildhall discussions were only the cruticle of a large amount of activity, and lectures, film displays, and visits to welfare institutions filled up a busy programme.

THE ROBERT JONES BIRTHDAY BOOK

THE dinner and presentation to Sir Robert Jones on his seventieth birthday, which was reported in our last issue, formed an occasion very unusual in this country. It was singular, in the first place, because only one speech was made and replied to, and in the second because the guest of the evening was presented with a collection of papers written for that occasion by his hosts and brother surgeons. *The Robert Jones Birthday Volume*,¹ as the book is called, contains twenty-five original essays by as many friends and admirers, and a preface by Sir Berkeley Moynihan, which we printed last week at page 30. In making the formal presentation of the book Sir Berkeley simply but eloquently expressed the feeling of all those present, as well as of many colleagues who could not attend.

Sir Robert Jones has endeared himself, by his charming manners and the native kindness of his nature, to everyone who has had to do with him, as much as he has aroused admiration and respect by his surgical knowledge and ability. For a good many years before the war he was highly thought of by orthopaedic surgeons in Europe, and still better appreciated by those in America. The war gave him the opportunity of serving his fellow men on a scale hitherto undreamed of—an opportunity which he seized with results which have long been celebrated. The work he did for the wounded in every field of battle where the Thomas splint and such like appliances had been used, and in the 35,000 military orthopaedic beds which were placed under his direction in the United Kingdom, spoke for itself, as his teaching did through the surgeons, both British and American, whom he trained. Only a man of extraordinary tact, power of conciliation, and sweet reasonableness could have done what he did in those eventful years.

Since the armistice he has not rested on his laurels, but has devoted his time and talents to the organization throughout the country of the care and cure of cripples, with a success to which many clinics and hospitals already bear witness.

It is perhaps well that the orthopaedic surgeons of to-day should be reminded that mighty men lived ere Agamemnon, and should be told of the achievements of their predecessors, some of whom made remarkable steps in advance, which often, however, led to little permanent progress, because the time was not ripe till Morton and his followers had abolished pain from the operation table and Lister had abolished suppuration from surgical wounds. Mr. Munro Little's opening paper on orthopaedics before Stromeyer should have such an effect, while at the same time it once more brings home to us how fleeting is surgical, and especially orthopaedic, reputation. Among the twenty-two clinical essays in the volume are six by leading surgeons of the European continent and America, one of whom, Dr. Mink Jansen of Leyden, has been so long closely associated with British orthopaedic surgeons that we hardly

think of him as a foreigner, since his devoted services to British sailors interned in Holland earned our hearty gratitude. His paper on dissociation of bone growth is a valuable and suggestive contribution to surgical knowledge and pathology. Professor Clarence Starr of Toronto is one of ourselves. He writes a pithy essay on a subject which he has made his own—that of acute infections in bone. He urges once more the importance of early recognition and early treatment of osteomyelitis.

In the scope of this notice it is impossible to do justice to a collection such as this, whose authors are all recognized authorities on orthopaedic subjects, and we can do little more than indicate them and recommend the study of the originals to our readers. Professor Osmond of Boston discusses the relations of intestinal stasis with spinal and sacro iliac arthritis, a subject which requires much investigation before any exact pathology is possible. Professor Pott describes cases of tumour of the femur and the extensive bone grafting operations which were necessary to fill the gap left by excision of the growths. Professor Hey Groves draws attention in a practical paper to the possibilities of cure of congenital dislocation of the hip which ought to be better appreciated by practitioners than they yet seem to be. Professor Nathaniel Allsopp of Harvard has chosen the open operations for the same deformity as his subject. He is not very hopeful in estimating the results of manipulative reduction, but favours open operation in many cases, or as a last resort, Lorenz's bifurcation operation. Mr. R. C. Linslie writes on fibrocystic diseases of the bones, a subject to which he has given much attention. Mr. Thurstan Holland of Liverpool gives us the benefit of an almost unequalled experience and keen observation and judgement in his well-illustrated essay on the accessory bones of the foot and some other conditions. The difficult subject (as regards treatment) of spinal fractures is discussed by Mr. A. Brownlow Mitchell of Belfast, with instructive illustrations. Mr. Harry Platt of Manchester draws upon his large experience of nerve injuries for his essay on nerve complications in injuries of the elbow. Mr. Faubank's paper on infantile or cervical coxa vara is full of interest, and should give its readers much help in the diagnosis and treatment of this deformity. Mr. McCine Aitken writes hopefully of the treatment of curvature of the spine, emphasizing the importance of the cultivation of postural reflexes in its correction, as well as plaster jackets. Mr. Rowley Bristow gives a good account of cysts of the semilunar cartilages of the knee, and well sums up the evidence for and against the various theories of their causation without being able to arrive at a positive decision. This paper is illustrated by colour prints of microphotographs as well as by ordinary photographs. Mr. Alwyn Smith of Cardiff offers many points of interest in his paper entitled "Sideights on knee-joint surgery," as does Mr. McMurray of Liverpool on the diagnosis of internal derangements of the knee. Mr. Blundell Bankart has written a practical paper on dislocations of the shoulder-joint. Dr. Calvé of Beck-Plage writes on infantile vertebral osteochondritis, Sir W. I. do Coney Wheeler on bone grafting in Pott's disease, Mr. Girdlestone on operations for tuberculosis of the hip, and Mr. Lanning Evans on astragalectomy, which operation he shows to have been practised as long ago as 1608. The paper of Mr. Naughton Dunn on arthrodesis of the tarsus for deformity, and that of Mr. Triethowan on fracture dislocation of the ankle-joint, are as practical and valuable as might be expected of surgeons of their ability and special experience.

The volume is appropriately wound up with an appreciation of Sir Robert Jones by Sir John Lynn-Thomas, who indicates from first-hand knowledge the part played by his friend in the marvellous development of orthopaedic surgery during and after the war.

SATURDAY, JULY 14TH, 1928

LUNACY LAW AND ADMINISTRATION

WISE WORDS TO THE PUBLIC

In the *Times* of July 4th and 5th Sir Frederick Willis, who recently retired from the chairmanship of the Board of Control for England and Wales, gave a few of the impressions he has gained during his seven years of office in that capacity. In these two articles he discusses matters of grave national importance, and these "impressions" will be justly appreciated as the weighty conclusions of one who has spent a lifetime in the public service with much distinction, latterly in a position which invests his utterances with exceptional authority.

Sir Frederick Willis has addressed himself to the general public, and it was no doubt fitting that he should say, first of all, that there is no foundation for the allegation that sane persons are frequently certified as insane and detained in mental hospitals or that cruelty to patients is practised in these institutions. Shortly after he entered on his duties, he says, grave complaints of this nature were made in certain quarters, frequently lurid details were given, but generally no information by which the institution could be identified. When the complaints admitted of investigation inquiries were made, and in every case it was proved that the charges were without foundation. The Royal Commission on Lunacy and Mental Disorder, it will be remembered, reported to the same effect, and it is to be hoped that, for a little while at least, the public mind may be set at rest on a matter with which all who have to deal with the care of the insane are well satisfied. Yet this same public, apprehensive and at times darkly suspicious of mental hospitals, has not been aroused as it should be, Sir Frederick says, on the whole subject of the incidence and treatment of mental disease. Indeed, he describes the attitude of the public to this most dreaded form of illness and to the supremely important matter of the mental health of the nation as one of singular apathy. "The view seems still to obtain that insanity cannot be avoided, that nothing can be done to prevent or cure it, and that all that can be done is to place sufferers in some institution where they will be looked after, and, unfortunately, in too many instances the friends then desire to forget all about them."

After paying a well deserved tribute to the mental hospitals of this country, which have evolved from asylums to real hospitals, with expert and specialist services and instructed and devoted nursing staffs, Sir Frederick Willis calls attention to the apparent fact that, notwithstanding the great improvements of recent years in the care and treatment of the insane, the incidence of insanity has not been materially reduced, nor has the recovery rate materially improved. In support of these serious statements he quotes official figures which show that the ratio of first admissions (the index to 'occurring' insanity) to all mental hospitals per 10 000 of population, which was 4.07 in the year 1869, 10.36 to 5.25 in 1919, and

with minor fluctuations declined to 4.48 per 10 000 in the year 1926. Similarly, with regard to recoveries the returns made to the Board of Control show that during the last twenty five years the recovery rate for all institutions has remained practically stationary at about 32 per cent of the numbers admitted. These figures, Sir Frederick Willis considers exceedingly unsatisfactory, especially in comparison with the marked improvement in the public health as revealed by the striking reduction in the general death rate from 22.4 per 1,000 in the five years 1846-50 to 10.9 per 1,000 for the quinquennium 1921-25. The only hope he sees of reducing the incidence of insanity and improving the recovery rate lies in so altering the law as to allow and encourage the early and skilled treatment of persons mentally ill.

Deferring for the moment any excursion into the very intricate subject of lunacy statistics, it is to be noted that in these two articles the late chairman of the Board of Control—himself a lawyer, a civil servant and, from the medical point of view, a layman—is urging the public to press for legal reforms which have been advocated time and again in the columns of the *British Medical Journal*, concerning which the whole medical profession is at one, and which were strongly recommended to Parliament by the Royal Commission on Lunacy and Mental Disorder in July, 1926. The law as it stands to day (and as it is likely to stand, Sir Frederick Willis thinks, until public opinion is fully aroused to the need for action) is a compromise between the principles of medical treatment and the cardinal legal principle of safeguarding the liberty of the individual to manage himself and his property. Unfortunately the compromise has a strong bias in favour of the latter principle inherited from the time when asylums were places of detention rather than of scientific treatment. The existing lunacy code, said the Royal Commission, bristles with precautions against improper detention, with the result that, whereas in every other type of institution for the treatment of disease the aim is to get in touch with the patient at the earliest possible stage, in the case of insanity the patient is not admissible to most institutions until the disease has so far progressed that he is a certifiable lunatic. Certification, the Commissioners said, should be the last resort in treatment, not its prerequisite. For this purpose they recommended a great extension to all mental hospitals of the voluntary system, whereby uncertified patients, able and willing to submit to treatment, might be admitted. This system is at present restricted in England and Wales to registered hospitals and licensed houses for private paying patients, and to two hospitals maintained with public money—namely, the Maudsley Hospital and the City of London Mental Hospital.

Apart from financial considerations, the extension of the voluntary system to public mental hospitals is not likely to provoke much opposition. The real bone of contention will be the further proposal to legalize the provisional or temporary treatment without certification in public and private mental hospitals, or, if the institutions meet with the approval of the Board of Control in general hospitals, nursing homes and single care of the involuntary mental case. In this connexion the term 'involuntary' for reasons which appeared to them sufficient was taken by the members of the Royal Commission to apply both to the case without volition and to the unwilling or resistant patient. No doubt the Royal Commissioners were correct in maintaining that even if there is no volition

the liberty of the individual is none the less infringed if he is removed and detained under treatment. It may be hazarded, however, that the assimilation of the non-volitional with the unwilling or resistant case contributed at least to the recommendation by the Royal Commission that a necessary preliminary for the treatment without certification of the whole involuntary class of patients should be the intervention of a magistrate. There can be no question that this procedure—the bringing in of the justice—will be regarded by the public as tantamount to certification, and if carried into effect will remove the chance of early treatment of mental disorder without certification from a considerable proportion of the very cases to whom it ought to be given. This is the criticism very cogently expressed in the report of the Lamer and Mental Disorder Committee of the British Medical Association¹ which will be discussed by the Representative Body at Cardiff in a few days time. The following words of the report of the Royal Commission seem very much to the point. But when all is said and done, reliance must inevitably be placed at some point on the skill and integrity of the medical man. If confidence is not reposed in the medical profession no system of protection can be devised which will not ultimately break down. If such confidence in the profession is well founded, the intervention of a magistrate becomes superfluous in all cases in which the patient does not deliberately resist treatment.

Unless the law is altered, says Sir Frederick Muls in conclusion, no improvement in the incidence of insanity or the recovery rate would seem to be likely.

The fact that we have failed to get the legislation necessary is at least an indication that public opinion has not been aroused on this subject as it should be. It is greatly to be hoped on every ground that his words will do something to shake the public out of its apathy.

BOVINE TUBERCULOSIS IN THE UNITED STATES

BOVINE tuberculosis has many aspects of interest to the medical man, not the least of which is the part it plays in causing disease in human beings. The bacillus can be conveyed to man both in meat and in milk, but as milk is the only animal food largely used in the raw state it is by far the more important. The value of a pure milk supply cannot be overestimated and it is of considerable interest to know what the United States are doing to produce this. Tubercle-free milk, in theory, need not necessarily be clean milk, and a tubercle-free herd of cattle is not necessarily a healthy one. Nevertheless, the work of the last ten years in America has shown that in practice, when a herd is freed from tuberculosis the general hygiene improves, the poor stock becomes weeded out, the milk yield increases in individual animals, and the bacterial purity of the milk improves enormously. At the same time the price of milk does not rise.

The general campaign in America takes two forms—antituberculosis work among stock and the passing of pure milk ordinances. In both respects it is recognized that little can be accomplished without the aid of the stock owner and the milk producer and so in all cases the first and probably the most important step is to educate the people generally. The forming of accredited herds was the first active step, taken ten years ago and the herds thus passed as free from bovine tuberculosis have increased from 204 in the first

year to 142,500 at the end of 1927, while nearly two million herds are under supervision. The accredited herd plan has now naturally evolved into an accredited men plan, and at the present time nearly one third of all the counties in the United States are either accredited or are under process of becoming so. One of the most active of the States in this work is New York, and some account of the methods adopted there may be of interest.² All testing is confined to areas—a township being the unit—and 90 per cent of the herd owners must sign up before testing commences. The test adopted is the ophthalmic intradermal one, as it is believed that the double method has definite advantages over any single method. Arrangements are made so that all the cattle in the unit can be tested in a week, and a sufficient force of veterinarians is employed to do this. All reactors are branded, segregated, appraised, and shipped to a public abattoir, where they are slaughtered. All infected premises are disinfected according to printed instructions and infected herds are retested at intervals of two or three months until a clean test is obtained. Even though no lesions are observed at necropsy, if one or more reactors are found the herd is treated as infected. All additions to herds must be made from other accredited herds, and after 90 per cent of cattle have been tested a quarantine may be instituted prohibiting the introduction of cattle which have not been tested within sixty days. Accredited herds are retested yearly. This plan has now been in operation for two years with very beneficial results, and over half the cattle in the State have been tested. It is estimated that by the year 1936 all the herds in the State will be accredited.

The other plan for the eradication of bovine tuberculosis is to a certain extent complementary. This consists in the adoption of pure milk ordinances, and so far more than 2,000 towns and cities have done this. In Chicago, for example, such a pure milk campaign has been instituted.³ All milk sold must be from healthy cows, and in spite of numerous objections from the milk trade and others this has been enforced. The supply has remained ample, while the consumption of milk has been raised by 15 per cent to nearly a million and a quarter quarts daily. The yield of milk per cow has increased and the price has remained at the old level (14 cents per quart). Improved quality and further safeguarding of the milk supply at its source have been secured through inspection of dairy farms. Tuberculin testing has become immensely popular, and it has been found that the cleaning up of the disease in cattle has been accompanied by a general improvement in hygiene and methods. Most striking of all, the bacterial quality of the milk has improved by 45 per cent during the past year, and infant mortality (children under 1 year) has decreased by 11.5 per cent, while deaths from enteritis and diarrhoea in children under 2 years have been reduced by 33.2 per cent. Similar results are reported from other localities, and many neighbouring counties and cities are following the examples set by New York and Chicago.

America is evidently taking this problem very seriously. Although the results of the strictly antituberculosis campaign will not be apparent for several years yet, the general improvement of milk has had an immediate and beneficial effect and this has provided us with an example which deserves the most serious consideration of those concerned with public health in these islands.

A TAX ON KNOWLEDGE.

THE idea of a tax on knowledge has ever been repugnant to the spirit of the British constitution, of which the House of Commons is the prime guardian, and it is therefore in keeping with tradition that a member of that House, Captain Ian Fraser, should have drawn the attention of the Chancellor of the Exchequer to the fact that the customs duty on imported cinematograph films operates as a means of excluding from this country certain films of high scientific value. A summary of the debate in the House of Commons appeared in our Parliamentary Notes last week (p. 37), from which it will be seen that Captain Fraser, who was supported by medical members of Parliament, proposed an amendment to exempt from duty films recording scientific investigation or research. The official reply was, in the first instance, to the effect that it would be impracticable to attempt to discriminate between "wholly educational films" and others. It seems possible that this view arises from the use of the word "educational" in the cinematograph industry to describe films of travel, of scenic interest, or of wild life, which are educational only in the broadest sense. Captain Fraser's amendment referred to films of the type described by Professor H. H. Turner of Oxford in a letter to the *Times* which appeared on July 3rd, relating in detail the almost incredible difficulty and delay which arose when a distinguished American astronomer, visiting this country on the invitation of the Royal Astronomical Society, brought with him two films of high scientific interest illustrative of his subject-matter—the atmosphere of the planets. One was intended for presentation to that society. Evidence that "Circumlocution Department" methods persist is given by the fact that, despite the ample assurance of the integrity of purpose of the owner of the films given by his sponsors in this country, dealings with seven successive officials were necessary before one of the films could be released on payment of the duty, amounting to 29s. Other items brought the total expense to about £4, and the second film was returned to America, the proceedings occupied between two and three days. Certainly, if the procedure adopted in this case, where there was no attempt at evasion, is essential, the administrative obstacles seem almost insurmountable. The complexity and absurdity of the business, however, really adds weight to the suggestion made in Parliament by Dr. Drummond Shiels, and developed by Captain Fraser, that the Customs administration should agree to accept certification by responsible scientific bodies, such as the Royal Society, the Royal Astronomical Society, or the British Medical Association, as evidence that certain films are worthy of exemption from duty. Mr. Churchill has undertaken that the question shall be reopened, and it is to be hoped that no opportunity will be lost by those interested in pressing the point at issue. The incidents quoted above—as well as others reported in the *Times* by Dr. R. G. Cantliff on June 27th and by the secretaries of the British Association on July 6th—make it clear that the duty on such films is a tax on knowledge, to be resisted by organized science with the same tenacity of purpose which animated a long-dead Scottish publisher at Greenock, in the days of the stamp duty upon newspapers, to produce his weekly journal printed upon cotton sheets and describe it as the *Greenock Aircs Clout*! The cinematograph is now not merely a valuable aid in medical education, it has already established itself as an instrument of precision in scientific research. In a matter of this importance it is the duty of the Treasury to override the objections of Customs officials, particularly when the films concerned, almost without exception, neither compete with any British commercial product nor offer any prospect of profit to their owners, their importers, or their users.

CRIME AND THE CRIMINAL.

IT is opportune, now that the public mind is seriously exercised as regards police organization and methods, and while the revival of Mr. Galsworthy's powerful play *Justice* has renewed thought and deepened concern with reference to prison conditions and their effect on the prisoner, that there should recently have been published for the Penal Reform Committee of the Society of Friends a pamphlet on *English Penal Methods*,¹ and in the well-known "To-day and To-morrow" series a little book by George Godwin entitled *Cain, or the Future of Crime*.² Both are short. The former contains only thirty-three pages of reading matter with a short bibliography, and the latter just over one hundred small pages, to which are added some twenty others advertising the series to which it belongs. The general content and main thesis of both publications are similar, but the pamphlet—less than half the length of the booklet, and only one-fifth its cost—is by far the clearer, saner, more logical, better arranged, more practical of the two. It claims, and in fact justifies its claim, to present for the first time within small compass an up-to-date outline of past and present aims in penal administration, to summarize the changing approach to the treatment of delinquency, and to outline what are held to be the most desirable and immediately practical steps in penal reform, and it does these things in a plain, orderly, and effective fashion. The booklet—in accordance, probably, with the aim and intention of the series to be startling, vivacious, whimsical, provoking—presents a very similar attitude towards immediate practical problems in a less balanced manner, and looks beyond these to a more remote and doubtful future when (if we follow the author aright) the chief crimes will be to be financially successful, to have no children, to beget children at too short intervals, or to have leisure, and when the chief punishments for these crimes will be for the State to appropriate accumulated individual possessions, to confiscate and rear children (occasionally allowing the mother to be its trustee), and to exterminate or at least sterilize the offenders. Society's attitude towards the criminal is here indicted as a relic of barbarism, the criminal is considered to be curable or incurable, and the duty of society to cure him if it can and to destroy him if it cannot. The more restrained manner is the more effective in calling attention to a practical problem and in pointing to a rational method of dealing with it. There are few thinking people who now dispute that the prime aim of punishment should be reform of the offender, his transformation, if possible, from a social liability to a social asset. This is not incompatible with the further object of protecting society—indeed, where possible it is obviously the best way of affording that protection. At first our prisons (except the debtors' prisons) were not places of punishment, but merely places of detention for those who would, when the judge came, be discharged, or hanged, or transported. The judge's business was to empty them, not to fill them. Later they became places for the incarceration of convicted persons as an alternative to transportation. Of recent years it has been increasingly the object to avoid sending offenders to prison at all when this can possibly be done, and to make the prison, when used, a place of psychological investigation, of educational work, and of reformatory intention. These objects are as yet, however, very imperfectly carried out, partly because public opinion and magisterial practice are not sufficiently enlightened, partly from other difficulties which are gradually being overcome. Children's courts and the treatment of young offenders,

¹ *English Penal Methods*. Published for the Penal Reform Committee of the Society of Friends. London: Friends Book Centre. Price 6d.

² *Cain or the Future of Crime*. By George Godwin. To-day and To-morrow Series. London: Kegan Paul, Trench, Trubner and Co., Ltd. New York: E. P. Dutton and Co. 1918. (Fcap. 8vo. pp. 108. 2s. 6d. net.)

the probation system, poor persons' defence, medical observation and report before conviction or before sentence, the imposition of fines with an extended time for payment, the remission to reformatory or Borstal institutions (though these are not in all respects suitable, and are in some degree still penal), are all proving satisfactory means of avoiding ordinary imprisonment. The effective application of the Mental Deficiency Act, especially in its recently amended form, will do much in the same direction. The use of specialized persons' education and reformatory work in prisons and prison visitation, are giving a more rational character to the detention itself, and such organizations as discharged prisoners' aid societies, with their more constructive recent methods, are helping to combat recidivism. The effects and still necessary developments of all these means are well set forth in the pamphlet under review, and, in addition, such subjects as capital punishment, preventive detention, and the indeterminate sentence are touched upon.

MINERS' PHTHISIS IN SOUTH AFRICA

Owing to the regrettable illness and retirement of Dr. Watkins-Pitchford from the chairmanship of the Witwatersrand Miners' Phthisis Medical Bureau, the publication of the annual reports on the work of the bureau during the last two years of his term of office has been delayed. They are now published in a single report by his successor, Dr. Louis G. Irvine, who has been first medical examiner to the bureau since its inception in 1916. This report follows the lines of the previous ones and is packed with information. Unfortunately, however, the information is so condensed that it is not easy for the casual reader to get a grasp of the medical problems with which the gold-mining industry of South Africa has to contend. It would be a great advantage if the more important features of the report could be set forth in a brief summary, and we should like to enter a plea that this be done in future years. The methods employed for diminishing the amount of dust in the air of the mines have been so successful that the old type of "miners' phthisis" is disappearing. The large, heavy lung with extensive fibrosis is giving place to the type in which the infective process plays the predominant part. Indeed, Dr. Watkins-Pitchford has expressed the opinion that in these days the development of what appears to be a simple silicosis is initiated by a tuberculous infection. Whereas in the past tuberculosis supervened upon silicosis, it is now believed that the processes are reversed, and that a retention of sputum in the lungs depends upon the presence of a tuberculous infection. Pathological confirmation of this view is still lacking, but it has at least the value of focusing attention upon the importance of the initial physical examination of all individuals applying for employment in the mines. During the ten years 1916-17 to 1925-26 there have been only ten cases of simple silicosis arising among "new miners," one case of combined silicosis and tuberculosis, and fifteen cases of simple tuberculosis. Taking into consideration the number of men employed, these figures are by no means excessive, and, if Dr. Watkins-Pitchford's views are correct, the continuation of a system of rigid initial examinations, combined with measures for the detection of tuberculosis in the earliest stages in individuals, should be followed by an even more satisfactory diminution of pulmonary diseases on the Rand. The bureau has always been justly proud of its x-ray service, and continued improvement in the radiographs is recorded in this report. The radiographs are controlled by clinical examinations and the pathological examinations of the lungs of diseased miners, but it is not clear whether this correlation includes the pathological examination of the thoracic viscera *in situ*. No doubt, for ordinary purposes,

examination of the lungs after removal from the body is sufficient, but for accurate control of the clinical and x-ray findings a careful inspection of the cadaver itself is necessary, and should yield extraordinarily interesting data. The work of the bureau is conducted on truly heroic lines, and throughout the whole report there is abundant evidence that the medical officers of the Rand, whether officials of the bureau or in the employment of the mines, are fully alive to their responsibilities. Not far short of a quarter of a million miners, Europeans and natives, are employed in the mines, and only a highly efficient organization could deal adequately with these numbers. The very satisfactory state of affairs revealed in the report is a matter of congratulation to all concerned.

TREATMENT OF PLACENTA PRAEVIA

The *Transactions of the American Gynecological Society* for the year 1927 maintain their usual high standard of interest and value. Communications on a variety of subjects are presented, and of the eighteen papers eight refer to obstetrical and ten to gynaecological conditions. The list of contributors includes many well-known names, such as Polak, Novak, Rubin, DeLee, Sampson, and Bill, but apart from the papers themselves great interest attaches to the discussions upon each separate paper read to the society. The transactions cover a wide field, for pathology, surgery, radiotherapy, and research have been dealt with in the year's work. To single out any one article for special comment is not easy, but Dr. Bill's communication on the treatment of placenta praevia is one of definite clinical importance. That most women who succumb to placenta praevia do so after delivery has long been recognized, and Dr. Bill asserts that injury to the placental site in the lower segment is the cause of the haemorrhage which so often proves fatal. Such injury may occur without any evidence of trauma of the cervix. Any treatment which will avoid such injury will give improved results, and accordingly Caesarean section is urged for all but the mildest degrees of placenta praevia. The statement is made that scant attention has hitherto been paid to the amount of blood lost before treatment is started, and a plea is therefore put forward on behalf of blood transfusion when carried out before delivery is begun. "No patient is delivered who has a blood count below 3 million reds and a blood pressure below 90-100 systolic and 60 diastolic, until blood transfusion has been given." Dr. Bill's results are very good both for mother and child, even admitting that all the cases were treated in hospital. Vaginal examination is not performed, in order to eliminate one great source of infection in such cases. The paper was well supported in the subsequent discussion, but more than one speaker remarked that podalic version was still the most useful line of treatment for patients who must be attended outside of hospital. The combination of blood transfusion and the Caesarean operation is not a fresh method of dealing with so grave an obstetrical complication as the one under discussion, but it is well that such procedures should receive the attention of the leading scientific societies.

A GUIDE TO SPECIALIZED INFORMATION

Few experiences cause more annoyance to anyone engaged in research or study than to reach the point when the available mine of information has been worked out to its last vein and one has not the least idea how to locate the next. The mineralogical metaphor is pardonable, for there is indeed a close resemblance between the geological structure of the earth's surface and the distribution and varying necessity of our stock of knowledge as embodied

in books and documents. There are large quantities like the British Museum library, capable of yielding more than a little of everything, there are mines useful for one particular subject, such as the libraries of the learned societies and trade organizations, there are rich inaccessible little veins in all sorts of unexpected places. Some of the deposits lie on the surface, some within easy reach, some are buried in the depths where only experts can locate them. The preparation of *The 14th Directory*¹ represents an effort to survey the field of written and printed knowledge as it exists in Great Britain and Ireland, and to furnish the seeker after truth with a map of the territory open to his exploitation. It is a work of reference of a type and scope which has often been envisaged but never realized in this country until now. A subtitle describes it as "a guide to sources of specialized information," but this is perhaps an understatement—the directory may well prove attractive to the general reader whose tastes are catholic, whose curiosity is easily aroused and who will be glad to know where he can find reading matter to satisfy his appetite for knowing a little about everything. Serious students will, however, be specially grateful to the Association of Special Libraries and Information Bureaux, from whose initials the book takes its uncatchy title, and whose efforts, with the financial assistance of the Carnegie United Kingdom Trustees, have made its production possible. Mr G. I. Barwick, Lit. Keeper of Printed Books at the British Museum, has acted as editor while Sir Frederic G. Kenyon and Sir Ernest Rutherford contribute short introductions explaining the genesis and aim of the work. In these days when scientific periodicals are numbered in thousands and new books appear in hundreds every month the value of one general index to existing collections of printed matter needs no emphasis. The compilers of the *14th Directory* have cast their nets wide but the mesh has been small: the range of subjects dealt with is therefore extensive. Entries under the letter "A" in the subject index include "amber" and "archery" as well as "aquiculture" and "anthropology." In format and typography the volume is well fitted to its purpose. The method of arrangement should make reference easy, the main part of the directory falls into three sections of which the first is arranged under subjects, the second under places, and the third is an index to names and named collections occurring in the two others. Information under subject headings includes, where appropriate, an indication of the nature, extent, availability, and location of known collections of material, a note of any useful source (for example, banks, consular agencies, trade organizations), a list of any periodicals dealing with the subject. The second section embodies similar information under the names of towns and villages, in some cases readers may be surprised to learn how rich are their local resources. It is probable that the appearance of this first edition will lead to an access of information to the association which will be embodied in future issues. Meantime it is intended that the material should be kept up to date in the office files of that body, where it is available for members. Both Sir Frederic Kenyon and Sir Ernest Rutherford, in their introductory notes, appeal for the co-operation of scientific workers and others in this enterprise, and their plea should find a ready response everywhere.

CANCER CONTROL.

In view of the International Conference on Cancer in London next week, to which we referred again on June 23rd (p. 1076), attention may perhaps be drawn to a paper by Dr W. B. Coley in the June issue of the *American*

Journal of Surgery. Dr Coley—whose interest in a possible bacterial cause of cancer is well known—discusses the problem of control in considerable detail. It appears that the American Society for the Control of Cancer has lately obtained a million dollars for endowment, and the question arises how the income from this fund can be most profitably laid out. He suggests that a substantial amount should be spent on collecting more accurate first-hand information about the geographical distribution of cancer, with special reference to its wide variation in incidence, and that propaganda among the laity, directed towards the recognition of early cases, should be supplemented by more instruction to medical practitioners in the diagnosis of malignant tumours. In his opinion it is better to place money at the disposal of hospitals and laboratories already established, and possessing clinical and laboratory staffs, than to use it in founding new institutions. As might be expected, Dr Coley advises further and more intensive research into the infective origin of cancer and the possibility of treating inoperable tumours—especially carcinomata—by bacterial toxins. He advocates a systematic attempt to obtain complete after histories of all patients treated for malignant disease in the leading hospitals of the world, and the publication of these and results so that some definite notion may be gained of the percentage of patients with malignant tumours who have kept well for a period of five years after treatment. As Dr Coley will be taking part in the forthcoming conference he may have an opportunity then of pressing upon his fellow workers the opinion stated in this paper, that international cancer congresses, for the interchange of experience and ideas, ought to be held at least every three years.

DAWSON WILLIAMS MEMORIAL FUND

MEETING OF SUBSCRIBERS

A GENERAL meeting of the subscribers to the Dawson Williams Memorial Fund was held at the hall of the Royal Society of Medicine on July 10th under the chairmanship of Sir HUMPHRY ROLLESTON. The purpose of the meeting was to hear a statement by the honorary treasurer (Sir STCLAIR THOMSON) and to decide on the form of the memorial. Among others present were Dr H. B. Blackenbury (Chairman of Council of the British Medical Association), Dr C. O. Hawthorne (Chairman of Representative Body), Mr W. McAdam Eccles, Mr H. S. Souttar, Dr William Hunter, Dr Charles Buttai, Dr H. W. Nott, Dr Alfred Cox (Medical Secretary British Medical Association), and Dr A. G. Horner (Editor, *British Medical Journal*).

Letters expressing regret at inability to attend were read from Lord Dawson, Sir Robert Philip (President of the British Medical Association), Sir Donald MacAlister, Sir James Berry, Mr V. Warren Low, Dr Andrew Balfour, Professor Fraser, Dr F. R. Fothergill, and a number of others, and several of these indicated their approval of the suggestion that the memorial should take the form of a periodical prize for the best work on pediatrics. Professor Blay Bell wrote that he thought it might be a condition of the prize that the work should be published in the *British Medical Journal* under a suitable heading to identify it with the memorial, and Dr Chalmers Watson wrote to suggest that the memorial should be in some way directed to the encouragement of the general practitioner, in whose interests Sir Dawson Williams laboured for the greater part of his working life.

A Prize for Pediatrics

Sir STCLAIR THOMSON reported that the contributors to the fund numbered 389 and the sum subscribed was £880, out of which a small amount—less than 5 per cent. of the total—had been expended on the necessary postages,

¹ *The 14th Directory*. Edited by G. F. Barwick, B.A. Introductions by Sir Frederic G. Kenyon, C.B.E., K.C.B., D.Litt., and Sir Ernest Rutherford, O.M., D.Sc. London: Association of Special Libraries and Information Bureaux, London, Edinburgh, and Glasgow: Oxford University Press, 1928. (7½ x 11¼ pp. xiii + 425. 2s. net.)

printing, and clerical work. The proposal of the Organizing Committee that the memorial should take the form of a prize, to be awarded every two years or at longer intervals, for the best work which had appeared on pediatrics since the previous award, was then considered. Sir HUMPHRY ROLLESTON said that this suggestion arose out of a remark by Sir Dawson Williams's successor in the editorship of the *British Medical Journal*, that disease in childhood was the subject which held Sir Dawson's special interest right up to the end of his life, and it was his desire, as expressed in their last conversation, that the then projected testimonial should take some such form. The interest on the money subscribed would be scarcely enough for a worthy prize to be offered annually, and therefore it was thought that it might be given every two or three years. The question was debated whether the prize should carry the obligation of giving a lecture, Dr HAWTHORNE pointing out that a lecture would have the advantage that it would appear as such in one or other of the medical journals, whereas in any other form the work might come within the cognizance of very few. Sir STCLAIR THOMSON suggested that the details should be left in the hands of the trustees to be appointed, and after some discussion, the main proposal of the Organizing Committee having been adopted, it was agreed to leave it to the discretion of the trustees as to whether they should ask the winner of the prize to give a lecture. The question whether the prize should be open to workers in all countries or restricted to the British Empire was discussed, and it was agreed in this matter also to leave the trustees unfettered.

Appointment of Trustees

With regard to the appointment of trustees, Sir HUMPHRY ROLLESTON suggested that in order to avoid the necessity of alteration of deed the trusteeship should be placed in the hands of those who for the time being held certain offices. He proposed, and it was agreed, that the trustees should be the Presidents of the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association, the Royal Society of Medicine, and the Section of Diseases of Children of that Society, together with the Editor of the *British Medical Journal*. Mr MOADAM ECOLLS asked whether the trustees would also be adjudicators of the award, to which Sir HUMPHRY ROLLESTON replied that no doubt, as was the practice in similar cases, they would refer the adjudication to a small committee. The Medical Secretary of the British Medical Association was appointed convener of the trustees, and it was agreed to ask Dr A. M. H. Gray and Mr Geoffrey Edwards, respectively honorary treasurer and secretary of the Royal Society of Medicine, to act as auditors of the accounts.

The proceedings closed with votes of thanks to the Royal Society of Medicine for the use of the premises, to Sir Humphry Rolleston for presiding, and to Sir StClair Thomson for his valuable services as honorary treasurer of the fund.

CENTENARY OF THE SHEFFIELD MEDICAL SCHOOL

SHEFFIELD is a city of recent growth in the industrial sense, although as a village it was famous for its special products in the time of Chaucer. With the industrial revolution of the nineteenth century it expanded rapidly and, from the health point of view, unfortunately. But it was among the first of the new industrial centres to realize the necessity for training medical men in the provinces. Its medical school, which celebrates its centenary this week, is junior only to Manchester and Birmingham among modern provincial cities.

Apart from its local interest the history of the medical school, written by the late Dr W. Smith Porter, and now published by the University, is an important contribution to medical history. Dr Porter's recent death robbed his colleagues and his many friends in Sheffield of a distinguished and much beloved personality. In addition to his eminence as a physician he was well known in literary and archaeological circles not only as an authority on the history of Sheffield, but as an expert on the history and the topography of Derbyshire. To tramp with Porter over the hills and among the dales and villages of Derbyshire and South Yorkshire was a privilege which only those who knew him can appreciate.

The history of the Sheffield Medical School was his last literary work, and, unfortunately, he did not live to complete it. It is probably also his best work, and should be widely read. His book shows briefly and vividly the condition of medical practice and education at the end of the eighteenth century and in the first half of the nineteenth century. It sets forth the gradual dawning of the public conscience to the fact that doctors needed some sort of decent training for their work, and that it was no longer desirable that such training should be available only to persons who could afford to go to London.

The Sheffield Medical School originated in the private enterprise of a Dr Overend, who was succeeded by his son, and who established a school, a museum, and a course of instruction in anatomy. They and their successors were intimately associated with "body snatching." Dr Porter makes it clear that Dr Overend ran his business as a "commercial proposition," although he was at the same time a pioneer in the teaching of anatomy and medicine in the provinces. The illegal acquisition of corpses, however, led to tumult and riot, then the principal method of argument among the inhabitants of Sheffield and the district. A medical school, of a more "official" character, was wrecked and burned a generation later, after the Burke and Hare revelations. But in spite of these manifestations of popular indignation, and the justification that undoubtedly existed for them—a Sheffield clergyman was imprisoned in connexion with abuses in his cemetery—there were ardent scientists and public-spirited and enlightened men in Sheffield, and the Sheffield School of Medicine was formed with new and more adequate premises in 1888. This became later the University College of Sheffield, and there is no doubt that the activities of the medical school had much to do with the final establishment of the Sheffield University in 1905.

Owing to the death of Dr Porter the record of the University has been brought up to date largely by Professor Arthur J. Hall, who has been intimately associated with its development. A handsome tribute is paid to the work of Sir John Robertson, who, as medical officer of health for Sheffield, was responsible for the establishment of what is now the department of pathology, and who brought about, while in Sheffield, the compulsory notification of tuberculosis, after proving by voluntary reports on a large scale that notification was the first essential step in any campaign directed against this disease.

The old Sheffield Medical School is now, of course, the medical faculty of the University and occupies a large part of the modern and handsome buildings which were opened by King Edward VII in 1905, having all the departments necessary to a modern medical school, fully equipped and up to date, as are the Sheffield hospitals. The teaching staff includes a number of men whose reputation is worldwide. That the Sheffield students enjoy facilities for training comparing favourably with those of any other teaching centre has been abundantly proved by the eminence which many of them have already attained in their profession.

In celebration of the centenary the University of Sheffield on Wednesday July 11th, held a congregation, and delegates from other universities, with representatives of the city and the University, were entertained at an official luncheon by the faculty of medicine. An account of the proceedings will be published in the next issue of the *Journal*.

BRITISH EMPIRE CANCER CAMPAIGN

ANNUAL GENERAL MEETING

The annual general meeting of the British Empire Cancer Campaign was held at the House of Lords on July 8th under the chairmanship of Sir JOHN BLAND SUTTON.

A letter was read from H R H the Duke of York, President of the Campaign, in which, after referring to the fact that during the year His Majesty had consented to become patron, he stated that the forthcoming International Conference which the Campaign had organized would be attended by 120 international and Dominion delegates, and nearly 300 delegates from this country. His Royal Highness was happy also to think that the various branches of the Campaign were all moving forward in the direction of research. The Birmingham Council was now established and doing valuable work, the Yorkshire Council had founded its research centre in association with Leeds University, the Lancashire, Cheshire, and North Wales Council, under the presidency of the Duke of Gloucester, had met with a splendid response to its preliminary appeal. Northumberland was contemplating the further augmentation of the research work being done at Newcastle under grants from the Grand Council. Further afield, the Irish and the New South Wales campaigns, both affiliated, were developing well, and a campaign had also been instituted in Queensland. The letter concluded: "I am happy to be your president, and I hope to occupy that office when the great work with which we are all associated is brought to a successful conclusion."

On the proposal of Mr CICIL ROWATREFF, the Grand Council was re-elected *en bloc*.

Sir CHARLES GORDON-WATSON, in proposing the adoption of the annual report, paid a tribute to Mr Lockhart-Mummery's editorship. As the document consisted of a series of reports from research bodies and individual workers, presenting at times conflicting views, it was no small compliment to Mr Lockhart-Mummery that during all the years he had carried out the editorial duties the reports should have been presented in so fair-minded a way that no note of adverse criticism had ever been raised. This was hardly the time to refer to the research in detail much as it would be laid bare at the forthcoming conference. The Campaign did not itself carry out research. Its carefully thought-out policy from its inception had been to bring together, in close sympathetic touch, the workers throughout the Empire. It prevented the overlapping of lines of research, checked all new work by counter-research, left no information or inquiry unconsidered, and gave financial aid and encouragement to accredited workers whenever the proposed research offered promise of fruit. He drew special attention to the radiological work at the Cancer Hospital at St Bartholomew's, in the latter a good deal of work on radium, which was hampered by the high cost of the material, was proceeding. Another feature of the report was the work done, after the Liverpool technique, on treatment by lead. Some two years ago the Campaign sent representatives to see Professor Blair Bell's work, and on their advice a grant was made to St Bartholomew's Hospital for research on the lead treatment of cancer. The report of the committee at St Bartholomew's was unfavourable to the method under test. On the other hand, some similar work in Birmingham had been more encouraging. He concluded by remarking that the Campaign rendered great service by disseminating with considerable rapidity all new results of research workers throughout the world. With regard to institutional provision for curable cancer cases, the transference of Maunty Verman from a Hospital for tuberculosis to one for cancer might help the situation considerably. On the financial side he mentioned how greatly the Campaign was indebted to Sir Richard Garton, honorary secretary and chairman of the Finance Committee through whose generosity the expenses of the International Conference would be met without infringing Campaign funds.

Sir RICHARD GARTON said that in the Campaign year (ending March 31st) the income exceeded the expenditure by £8,822 but this result was due to the munificent gift of

£10,000 from an anonymous donor. The cost of appeals was only 8.6 per cent of the money received in donations. He added that £150,000 had been raised for the Yorkshire campaign, and £100,000 for that of Lancashire, Cheshire, and North Wales.

Afterwards, at a quarterly meeting of the Grand Council, the Marquess of Reading was elected chairman in succession to the late Paul Cave, and Lord Dawson of Penn and Sir John Bland Sutton were elected vice-chairmen.

The outstanding features of the annual report are mentioned in the above proceedings. On the subject of lead treatment, the standing committee of the Council of St Bartholomew's Medical College reports conclusions highly unfavourable to the method. The committee states that so far as its limited investigation goes, no evidence has been obtained that the use of lead by intravenous injection leads to the resorption of neoplastic tissues in man. It also reports that the average duration of life of the patients treated by lead was less than their expectation had they not been so treated. On the other hand, as Sir Charles Cawdon-Watson stated the Birmingham Cancer Committee has been conducting an experimental inquiry into the value of colloidal lead compounds in the treatment of malignant disease, and reports provisionally that of 34 cases treated 10 derived benefit, and that there is warrant for the opinion that the method is of distinct therapeutic value and deserves further investigation. The main therapeutic value of lead, say these workers, appears to be in its ability to restrain metastases or to destroy small and recent deposits of growth. In addition, the report embodies statements on various lines of cancer research from institutions receiving grants, including the research departments of the Cancer Hospital, St Mark's, the Middlesex, and Westminster Hospitals, the Christchurch Hospital, Manchester, and the Cancer Research Committee of the London Association of the Medical Women's Federation. Reports are also forthcoming from various individual workers, notably Dr Thomas Lumsden, working at the Fister Institute. Dr Lumsden and his assistants have been extensively investigating the feasibility of producing a vaccine against malignant tumours. If appropriate cases can be found the answer to the question whether vaccine treatment will cure spontaneously occurring tumours, and especially the tumours of man, should, according to Dr Lumsden, be forthcoming within the next year or two. It is stated that the total sum expended by the Campaign on research work during the past year approximated £20,000, and that with the opening of new centres of research the financial needs have increased rather than abated.

THE MANCHESTER CANCER CAMPAIGN

The campaign against cancer recently inaugurated by the Manchester Committee on Cancer may be regarded as having been a genuine success from many points of view. The medical profession of the city and the civic authorities are to be congratulated on their co-operation in an endeavour to fight the evils of this scourge.

The campaign began in July, 1924, with the establishment of a provisional committee by Dr Veitch Clark, medical officer of health for Manchester, and after several meetings it was reconstituted in December of the same year in such a way as to connect it with the various bodies in the city concerned with the many aspects of cancer. It then consisted of lay and professional representatives from the Public Health Committee, the University, the Royal Infirmary, and other large hospitals in the district. Its object was to centralize the efforts being made in cancer research and investigation. A sum of £12,500 was raised and a scheme of work put into operation.

The committee decided to concentrate upon three lines of activity—laboratory research, inquiry into the results of cancer treatment, and distribution to all sections of the community of up-to-date information upon cancer, which included a course of post-graduate lectures for medical practitioners and were delivered by specialists in the particular subjects dealt with. These lectures are now published

In an attractive book form,¹ which has just reached us, together with a survey of the work of the special investigation officers into the results of treatment of cancer of the breast. The manner in which the work has been conducted is particularly to be commended, and the institution of such propaganda must call for the cordial approbation of the Ministry of Health.

The course of lectures was opened by Dr Veitch Clark on October 1st, 1926, who chose as his subject the general survey of the incidence of cancer. After approaching the subject from a statistical and also from a medical aspect, he comes to the only possible conclusion, that the increase in cancer is a definite fact in most countries, not only in Europe but in the Far East as well. He emphasizes the incidence of cancer from 45 years upwards, and the higher rate of prevalence in women due to cancer of the mamma and generative organs. He deals with the various aspects of occupational cancer, and shows the enormous preponderance of cancer incidence amongst cotton operatives.

The subject of mule-spinners' cancer, which is so closely associated with the Lancashire cotton industry, is dealt with more fully in lectures in the same series by Dr Henry, Mr A. H. Southam, and Dr Twort. Mr Southam's lecture, which deals with the clinical features and treatment of the disease, has already been published in our columns.² This is one of the most favourable types of malignant disease, as it can be detected in an early stage and can then be cured by radical removal. Dr Powell White summarizes the modern views as to the causation of cancer, and after discussing Gye's hypothesis states that, in all probability, tissue culture experts will assist us in finally solving this difficult problem. In dealing with the idea of cancer houses and cancer districts he finds the evidence very insufficient and unlikely to satisfy anyone accustomed to weighing up the value of evidence. Professor Jamieson, in his lecture on the lymphatic system, reminds us that a close and accurate knowledge of regional lymphatic anatomy is necessary for good operative work. It appears probable that many cancer cells are killed in the glands, but it is only too obvious that some survive and form secondary tumours. The important point is to regard the spread of a tumour as evenly centrifugal, and consequently that the glands are not likely to be affected by other means than this peripheral permeation. The permeation theory is an extension of our knowledge, and no operation can be regarded as truly radical unless the tumour, a wide area round it, the lymphatic trunks of the areas, and the lymphatic glands are removed. Professor Burgess deals with cancer of the gastro-intestinal tract, and emphasizes the importance of the early symptoms and the early diagnosis of cancer in this situation. In referring to the great frequency of cancer of the stomach he does not regard pre-existent ulceration as an important etiological factor. This view is supported by clinical experience, and is of great practical importance in the surgical treatment of gastric ulcer.

With the mastery of the technique of radiotherapy we may look forward to a new era in the treatment of malignant disease, and it is probable that in a few years radium will be recognized as the best form of treatment for certain types of cancer—for example, cancer of the tongue, rodent ulcer, and epithelioma of the skin. The use of radium and x rays in the treatment of cancer is dealt with by Dr Burrows, and his results, whilst working in Manchester, show 10 per cent of apparently permanent cures in what were nearly all inoperable cases. In carcinoma of the cervix 30 per cent of inoperable cases cleared up, but about 15 per cent of these recurred at a subsequent date. Professor Donald, however, prefers operation to the use of radium in those cases where there seems a reasonable chance of total extirpation of the disease, and does not agree with American gynaecologists with whom the use of radium in the treatment of uterine cancer has largely supplanted operative treatment.

The main line of experimental research which has been

¹ Lectures on cancer also special report on the results of operation in cases of cancer of the breast. Published by the Manchester Committee on Cancer.

² British Medical Journal February 26th 1927.

undertaken by the Manchester committee has been in connexion with the origin and prevention of mule spinners' cancer. The scientific staff, working in the laboratories at the University of Manchester, have examined different samples of lubricating oil used in cotton mills, and have produced cancer in mice with the oil actually used in cotton mills, which confirms the view that mule spinners' cancer can be produced by a mineral oil. Further, it was found that shale oil was much more liable to produce cancer than a shale-free petroleum oil, and a lubricating oil made from sperm oil was quite harmless. Observations were made also on toxic oils purified by various methods, with interesting results. Samples treated with sulphuric acid were rendered harmless, and one process has been found which may be of commercial value. In addition, research work on the investigation of the cancer producing qualities of a special form of tar gave striking results—namely, 100 per cent of tumours appeared in mice in seventeen weeks.

The report contains also the result of the special statistical inquiry carried out by the full time investigators appointed by the committee—Dr Greta Wardle and Dr John Murray. These officers have been conducting an inquiry into the later history and results of treatment of cases of cancer of the breast treated during the two periods 1910-13 and 1919-21. The work appears to have been carried out with great care and exactness, and was based primarily on the pathological diagnosis to ensure correct diagnosis. In all 521 cases were investigated, 375 being cases of primary tumour in which the growth was proved histologically malignant. The report shows clearly that when cases of cancer of the breast are treated by modern surgical methods in the early stages the outlook is very hopeful—over 80 per cent being alive at the end of ten years after the operation. When the axillary glands are involved treatment appears to offer three years of life to 50 per cent, five years to 33.3 per cent, and ten years of life or more to 20 per cent. The majority of the cases under review were suffering from cancer of the spheroidal-celled type. The report emphasizes the importance of the early recognition of the disease and of immediate operation by surgeons who are experienced in this type of work.

The production of a book such as this is specially to be commended, for it must serve to concentrate attention on the different aspects of the cancer problem, and it may be expected to bear good fruit in the future.

THE SCIENTIFIC CONTROL OF LIQUOR CONSUMPTION

At a meeting of the Society for the Study of Inebriety, on July 10th, Dr H. M. VERNON, investigator for the Industrial Fatigue Research Board, expounded a scheme for the control of alcoholic drinking by what may be called scientific taxation. Dr Vernon reminded his audience that during the war several restrictions on the production and sale of alcoholic liquors were introduced by the Liquor Control Board, and made for the sobriety of the nation to an extraordinary degree. The restrictions were based largely on a scheme of physiological regulation, the object of which was to diminish alcoholism by modifying the conditions under which drink could be procured. Before the war alcoholic liquors were on sale continuously from sixteen to nineteen and a half hours a day. This was reduced by the Board to five and a half hours, no liquor was obtainable before mid day, so that almost inevitably the first liquor taken in the day was taken with food, and was thus rendered less harmful, public-houses were closed during the afternoon, which resulted in the prevention of soaking. The total supplies of liquor were also reduced owing to food shortage. The result of all this was that by 1918 the convictions for drunkenness had fallen to 17 per cent of their pre-war number, and the deaths from alcoholism showed a similar fall. In this connexion it may be mentioned that Dr Vernon was criticized in the subsequent discussion for not taking into account the fact that during this period a large part of the male population of the country was abroad on service or under discipline at

home Dr Vernon went on to say that any such restrictions would be difficult to apply in peace time, but there was a method of control, through taxation, which could be instantly applied on any Budget. At present though the expenditure per head on alcoholic liquors was 15 per cent above its pre-war level, the amount of alcohol consumed was only 55 per cent as great, and the convictions for drunkenness were 41 per cent of the pre-war figure. Taxation of liquor was now so high that any alteration was likely to be in the direction of remission rather than of increase, but by adopting a scientific scheme of differential taxation the very remission of taxation on intoxicating liquors could be made in such a way as to reduce intemperance. The principle of this scheme was that dilute liquors were far less deleterious than concentrated liquors, therefore the sale of these dilute liquors should be encouraged by lightening the tax, while the tax on concentrated liquors should be increased. As the result of a long series of experiments he had shown that beer containing 3 per cent of alcohol by volume was non-intoxicating, and he suggested that the tax on such liquor should be lowered, while the tax on strong beer (5.7 per cent of alcohol) should be raised, and that on average beer (4.6 per cent) should remain as at present. The present tax on wines he thought absurdly low, for, reckoned in proportion to their alcoholic content, it was no more than the tax on beers. On the other hand, the average spirit drinker who was accustomed to dilute his spirits with two to four parts of water, and thus reduce them to the alcoholic strength of wine, was heavily overtaxed. As nothing should be done to encourage the consumption of neat spirits, Dr Vernon suggested that spirits should be issued at two concentrations very differently taxed. Instead of the present tax of 72s 6d per proof gallon (spirits at 60° under proof (only slightly more alcoholic than port) should be taxed at 50s per proof gallon (or 20s per actual gallon), while spirits at 30° under proof (the strength now customary) should be taxed at 95s. Dr Vernon's suggestions are best appreciated by the following table

Liquor	Per cent alcohol by vol	Present Taxation		Suggested Taxation	
		Per gallon	For each % of alc	Per gallon	For each % of alc
Very weak beer ..	2.9	£ 0 10	3.4d	£ 0 4	1.4d
Average beer	4.6	1 8	4 d	1 8	4.3d
Strong beer	5.7	2 3	4.7d	2 9	5.8d
Claret ..	10.3	3 0	3.5d	6 0	7.0d
Port and sherry	20.0	8 0	4.8d	15 0	9.6d
Spirits 60° u p	22.8	—	—	20 0	10.5d
Spirits 30° u p	40.0	10 9	15.2d	66 0	33.0d

In the ensuing discussion the chief criticism was that the cause of temperance was not necessarily served by making even a lower strength of beer comparatively cheap

India.

Future of Medical Research in India

As previously mentioned in these columns an endeavour to improve medical research in India is engaging the attention of the central Government, and an inquiry into the matter is being conducted by a committee with Sir Walter Fletcher as chairman. It may be recalled that under the diarchical constitution medicine and public health are 'transferred' subjects (that is, they are entrusted to the provincial Governments), while medical research is among the subjects reserved to the central Government. In the annual report for 1927 of the Calcutta School of Tropical Medicine, the director, Lieut-Colonel J W D Megaw, I M S, records the views he expressed to the members of the Fletcher Committee on the occasion of their

visit to the school last January, his notes throw an interesting light on to the general question and on to its relation to the Calcutta school. The school, though primarily a Government of Bengal institution, actually serves all parts of India, its researches relate to problems arising throughout the sub-continent, and its students are drawn from almost every province and state. Colonel Megaw indicates its deficiencies in respect of personnel and organization, and suggests the steps that should be taken to remedy these. He believes that the most profitable line of development for medical research in India lies in the expansion of existing institutions rather than in the creation of new centres, and that the greatest need is for men rather than buildings. It is suggested that the Calcutta school provides a natural centre for future development. To secure co-ordination of research, however, Colonel Megaw believes the establishment of a central bureau, as distinct from a new research institute, would be desirable, the bureau would be associated with the Government of India, would accommodate the secretariat of the Research Fund Association, be responsible for all research and propaganda work, and serve generally as a nerve centre of medical research. The need for encouraging suitable men to undertake research work is emphasized, and various proposals are outlined. In dealing with the present position of the Calcutta school it is stated that the most important deficiency is the absence of a department of bacteriology, though the creation of a chair of helminthology is also necessary. Reference is made to the question of higher teaching and research in public health. The school is at present the only institution in India properly staffed for the training of men in the routine work of public health but it can admit only a limited number, an increasing proportion of those who desire training have to be rejected each year owing to lack of accommodation. As at present constituted the Calcutta institution can deal only with candidates from Bengal and those provinces which contribute to its funds, and Colonel Megaw suggests that if adequate provision for research and specialized training in public health is to be made a new school of hygiene for all India should be established.

Prevention of Cholera in Bihar and Orissa.

The provincial death rate from cholera rose in the province of Bihar and Orissa during 1926, the mortality being worse in the district of Patna and in certain towns. A sharp outbreak occurred in the Purnea district early in April, but prompt steps were taken and the epidemic was cut short. In his annual report for 1926 Lieut Colonel J A S Phillips, I M S, director of public health for the province, gives an account of the preventive measures which are adopted in connexion with the fairs and festivals. A special staff is provided for the cholera hospital at Puri, and additional medical officers are appointed to supervise the general sanitation of the town, where three great festivals are held in June, July, and November. The town is regarded as consisting of five areas, with an epidemic officer in charge of each, and working in co-operation with the chief health officer and his sanitary staff. The pilgrims are accommodated in lodging houses for the most part, which are cleaned and whitewashed and then licensed by the health officer for the number of pilgrims allowed to occupy them. Each epidemic officer is given a small headquarters in the centre of his area, where disinfectants are stored and the police and sanitary staff can report the occurrence of any form of epidemic disease. His duties include daily examination of the lodging houses in his area, supervision of the disinfection of wells, removal of cholera patients to hospital, and the purification of their dwellings. On one occasion when infection was imported into Puri just before a fair several persons contracted cholera, but they were so promptly dealt with that no second case occurred in any one lodging house. In another town a temporary cholera hospital was erected, consisting of grass huts. In this province the disinfection of wells is effected by chlorinated lime, a great advantage of which is that it can also be used for treating cholera dejecta, so that it is not necessary

to carry more than the one disinfectant to a village where an outbreak occurs. The use of potassium permanganate is not possible for the disinfection of wells, the inhabitants objecting, presumably because it colours the water. Bleaching powder, properly stored, is considered much superior to potassium permanganate, but if carelessly kept becomes inert. Ample supplies of cholera vaccine are kept at the vaccine depot at Naunkum, and civil surgeons are supplied with reserve stocks of kaolin and disinfectants so that they can act immediately when cholera appears.

Civil Hospitals in Burma

An increase in the incidence of cholera in Burma has led to the suggestion that an inquiry should be set on foot into the prevalence of seasonal variation of this disease. There were in 1926, according to the report on hospitals and dispensaries prepared by Lieut Colonel L. E. Gilbert, I.M.S., officiating Inspector-General of Civil Hospitals, 1,208 cases treated as against 378 in the previous year. The death rate among in-patients was 46 per cent. Dysentery cases also showed an increase, the total being 27 per cent higher at 36,744, the disease was largely water-borne, and its prevalence is attributed to the backward state of the water supplies. The number of patients dealt with in civil hospitals was 2,157,446, an increase of 93,923, of the total 2,063,523 were outdoor patients. Reference is made to the system of treatment by subsidized medical practitioners, the cost to the Government being about forty rupees for each twenty patients. This is described as "a very high figure," but it is regarded as too soon to pronounce a final opinion on the working of the scheme. Special clinics for venereal diseases and leprosy were opened during the year, details of the latter were published on January 22nd, 1927 (p. 158). At the end of the year there were 285 hospitals and dispensaries open, an increase of four on the previous year. Many schemes of hospital reconstruction have been delayed owing to the decision of the Government to contribute only one third of the cost, local bodies being unable to find the balance, but in several important cases good progress has been made, notably in the construction of the Dufferin Hospital for Women in Rangoon and of the new mental hospital at Tada-U.

Radium Institute Removed from Ranchi to Patna

The Radium Institute, formerly situated at Ranchi, has been transferred, by instruction of the Government of Bihar and Orissa, to Patna, where it will, for the present, be housed in rooms forming part of the Patna General Hospital, the institute will have at its disposal in the hospital separate accommodation for its patients. This change has been made partly because of the difficulty of reaching Ranchi from Northern India, but also because it is believed that both the institute and the hospital will benefit from the closer co-operation which will be made possible by their proximity. The radiological experts of the institute will henceforth be able to work in collaboration with the physicians and surgeons of the hospital staff. It is also believed that it will be of advantage to the medical college attached to the hospital to have available for its students the facilities for instruction in the employment of radium which the institute can afford.

A Tuberculosis Sanatorium in Madras.

The foundation stone of a sanatorium for the treatment of tuberculosis was laid on April 11th at Tambaram, Madras, by Sir C. P. Ramaswami Aiyar, who made an appeal for public support. The project owes its origin to Dr. D. C. Muthu. It is intended to create a garden colony at the new centre, to provide treatment for tuberculous patients, and to undertake preventive and educative work. An area of 300 acres is available for the development of the colony, which is designed to afford full scope for all forms of open-air activity on an extensive scale. Dr. Muthu contemplates also the establishment of a similar colony at Bangalore.

Ireland.

Rotunda Hospital, Dublin

In his first annual report, dealing with the year 1927, Dr. Bethel Solomons, Master of the Rotunda Hospital, mentions that the outstanding feature during the period under review was the installation of the x-ray plant. He adds that this new department has already been found most useful in obstetrical diagnosis, especially for the performance of pelvimetry, as well as for gynaecological diagnosis and treatment. The scope of the ante-natal department has been considerably increased. Dr. Solomons revived the "Rotunda estimation," which was originated by Dr. Tweedy, and the percentages of this and of the British Medical Association standard are exactly the same—a coincidence which never occurred in the many years when this estimation was previously employed. The number of Caesarean sections increased, partly in consequence of facility of transporting patients. The lower segment was chosen for the operation site whenever possible. Dr. Solomons refers to the paper he read on this subject in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association at Edinburgh (see *Journal*, November 19th, 1927, p. 921). He comments in some detail on various outstanding features of the clinical work of the year under review, and mentions twenty-three cases of accidental haemorrhage and thirty of placenta praevia, all without mortality. The 381 patients admitted to the wards with albuminuria all recovered, except one who had hyperemesis. The report includes an interesting table of cases of disproportion between the foetus and the mother. It is stated that whenever possible the pelvis is measured with the Skutsch or Tottenham pelvimeter, and outlet measurements are taken. The Müller-Kerr estimation has been performed as a routine, and a modification of it is being tested, a trial of labour is allowed when advisable. The infant's head is now measured as a routine procedure after birth. Forceps were applied 131 times, or in 6.6 per cent of the cases. The number of patients (673) admitted to the gynaecological wing during the year constituted a record. Many cases of sterility were dealt with, and the tubes are tested as a routine procedure whenever doubt exists. The pathological laboratory was reopened in February, 1927. During the previous seven years these investigations had been entrusted to the Trinity College laboratory, but the need was felt of pathological facilities in the hospital itself. Dr. F. S. Bomke contributes a description of the various examinations made. The report contains an abundance of instructive tables relating to the obstetrical and gynaecological departments of this famous institution.

New Maternity Hospital for Belfast

At a meeting in the Belfast City Hall on June 29th, Colonel Forrest, superintendent of the Belfast Royal Victoria Hospital, announced that, as a result of the appeal made by the Duchess of Abercorn, the sum of £18,600 had been raised for the building fund of the new maternity hospital. The Lady Mayoress stated that she had undertaken to take charge of the collection of money in Belfast with a view to raising the necessary funds for the maintenance of the new hospital. Professor Lowry, commenting on the necessity of an up-to-date maternity hospital, said that it would not only help to save the lives of mothers and children directly, but would be of great assistance in the training of medical students and maternity nurses. Colonel Forrest remarked that they needed a hospital which would help in saving lives and in the training of students and nurses, it was not to be a barrack nor a mere ornamental building. A maternity hospital required 70 per cent more nurses than an ordinary hospital.

Amalgamation of Hospitals

The annual report of the Meath Hospital showed that the income for the year was slightly in excess of expenditure. The overdraft at the bank on March 31st was £4,744, as compared with £5,003 in 1927. The total expenditure

was £14,300, and the income £14,627. There were in the wards on April 1st, 1927, 120 patients, 1,787 were admitted during the year, making a total of 1,907. Of these, 1,679 were discharged cured or relieved, 106 died, and 122 remained in hospital on March 31st, 1928. The total number of days spent in hospital was 43,274, the average daily number of beds occupied was 118.55. The average number of days spent by each patient in hospital was 22.66, and the mortality was 5.75 per cent on the total cases treated to a termination. There were 5,027 accident cases treated as out-patients, and the dispensary cases numbered 16,123. There was thus a grand total of 23,057 persons who received medical or surgical treatment during the year. The report added that the hospital had suffered a very severe loss through the death of Dr. Richard Lane Jovitt, who had inaugurated the tin-foil collection, it was due entirely to his efforts that the hospital benefited by some hundreds of pounds. The committee acknowledged their indebtedness to the Dublin County Council for giving, in addition to their annual grant of £1,000, a bonus of £1,800, and to the Commissioners of the county borough of Dublin for their grant of £400. Dr. W. Bownell moved the adoption of the report and Sir John W. Moore seconded. The chairman, Mr. William Stewart Collis, said that all the hospitals in turn were making appeals for funds. He feared that they were falling behind in the general advance of medical science as regards housing of the sick, teaching, and research work. This was chiefly due to lack of organization and money, and if these hospitals were to maintain their existence in the front rank they must reform and come into line with those of other great cities. It was obvious, too, that there were medical students scattered in a number of small hospitals who could not have the same opportunities for learning as in a central hospital with five times the number of patients. The chairman compared the hospitals in Dublin with those in Belfast, and added that this difficult and important question was being considered, and that financial help was being sought in other quarters.

Tuberculosis in Waterford

Dr. Hogan, tuberculosis officer for the borough of Waterford, in his annual report states there has been a steady decrease in the death rate from tuberculosis in the city. Dr. Hogan urges that a sanatorium for the treatment of advanced cases only would never be popular, as the mere mention of such a condition was looked upon by the patient as a sentence of death. An institution was required where early cases, advanced cases, middle cases, and even surgical cases could be dealt with. Dr. Hogan remarks that in old cities like Waterford, where so many small houses exist, it is virtually impossible to eradicate the disease, the presence of one tuberculosis patient in a house is sufficient to infect all the other members of the family. The original victim is often not aware of his condition for years, during which his relatives have become infected, some fatally. Notwithstanding their efforts the incidence of the disease was far greater than could be wished, but that was not surprising in view of the number of small houses and the amount of poverty in the city.

International Convention on Cancer

The Minister for Local Government and Public Health (Irish Free State) has appointed Dr. Maurice R. J. Hayes of Dublin to represent him at the forthcoming International Convention on Cancer, to be held from July 16th to the 22nd in London at the House of the Royal Society of Medicine. Dr. Hayes is the President of the Leinster Branch of the British Medical Association.

Public Health Congress in Dublin

The Royal Institute of Public Health has now issued the preliminary programme for the annual congress, to be held this year in Dublin, from August 15th to 20th inclusive. His Excellency the Governor-General of the Irish Free State has accepted the office of honorary president of the congress, and General Richard Mulcahy, Minister for Local Government and Public Health, that of president. Reference to the work of the Institute and to the arrangements for the congress was made in an address

by Sir William Thompson, M.D., reported in the *British Medical Journal* on May 5th (p. 770). Detailed sectional arrangements will be announced at a later date by the Institute. Meanwhile it may be stated that the scientific proceedings will be organized in five main sections, the first, devoted to State medicine, having as subsidiaries two subsections, dealing with municipal and county sanitation, and epidemiology respectively. Bacteriology, pathology, and biochemistry will furnish the subject-matter of the discussions in the second section, and the third will be concerned with maternity and child welfare, and school medical inspection. The fourth section will deal with the production and control of milk and food—a subject which should provoke considerable interest in Ireland—and the fifth with tuberculosis. An interesting programme of supplementary events—official entertainments, social functions, visits to places of interest, etc.—has been arranged, and a large number of the leading figures in the realm of public health and allied sciences, from Great Britain and abroad, will attend. The Council of the Institute extends an invitation to all who may be interested to attend the congress. Information may be obtained from the honorary secretary, at the offices, 37, Russell Square, W.C.1.

Scotland.

Health of Edinburgh

THE annual report of Dr. William Robertson, medical officer of health for Edinburgh, dealing with the year 1927 was issued last month. The population of the city, estimated to the middle of the year, was 425,147, with a density of 13 persons per acre, and the number of inhabited houses was 104,488, the birth rate was 19 and the death rate 14.3, while the infantile mortality was 80 per 1,000, the same figure as in the preceding year. Emphasis is laid on the fact that in Edinburgh, as in other large centres of population, too many children under 1 year of age are still dying, although considerable reductions of infantile mortality have been effected and although last year the Edinburgh figures were below the average for other cities in Scotland. During the year there were 219 deaths from epidemic diseases including enteric fever, scarlet fever, diarrhoea, enteritis, whooping-cough, measles, and diphtheria, out of this total 114 deaths, or more than half, were due to whooping-cough and measles. Mention is made of the great difficulty found in preventing the spread of these diseases when they invade the community. Of the deaths 43 were due to diphtheria, the same number as in the previous year. Attention is drawn to the fact that payment is received by medical practitioners for submitting swabs from persons who have been in contact with this disease with the object of recognizing carriers who might convey the disease to school. The total amount paid in 1927 for these swabs of "contacts" was £103 7s, but it is pointed out that this outlay probably saved much larger sums which would have been required for the treatment of infected persons in hospital. Immunization of children is also being continued, and the facilities offered in this way have been very considerably utilized by citizens of Edinburgh for their children. During 1926 the toxin-antitoxin mixture previously used for diphtheria immunization was replaced by toxoid-antitoxin which is not liable to dissociate on keeping. Among 11,608 children who had been found to be immune or had been protected in this manner 58 cases of diphtheria occurred, but none of these was fatal, while in the same period 2,741 cases had occurred among children who had not been immunized, and of this number 242 had died. With regard to venereal diseases reference is made to the refusal of the House of Commons to allow a second reading of the bill promoted by the Edinburgh Corporation, the report points out that certain forms of the disease are on the increase, notwithstanding all efforts to educate the public, and the need for legislative measures to deal with this problem is urgently pressed. Although there has been progress in dealing with the housing problem there are still 7,328 single-roomed houses in the city, while approximately 12,000 houses are

still occupied at rents below £10, and 22,922 houses with rents between £10 and £15. There is a great necessity for providing low rented houses for low wage earners, especially for those who have larger families than can reasonably be accommodated in two roomed houses. Good progress has been made during the year with the erection of new houses under the various corporation housing schemes, a total of 5,899 houses having been constructed. Regret is expressed in the report that the question of a grant stands in the way of the hostel proposed for single men. In regard to hospital services attention is drawn to what has been done by the city of Aberdeen in co-ordinating the services of various hospitals within the municipal area, and it is added that this step will be forced on local authorities in the near future. With regard to maternity and child welfare, a scheme started in 1917 for the supervision of children through the ante-natal period and up to 5 years of age is subsidized, half by the corporation and half by the State. The percentage of births which had received ante-natal supervision at the centres had increased from 20 per cent in 1921 to 44 per cent in 1927. The number of attendances during the year at eight centres had been 15,417, as compared with 10,777 in 1926. Eight preventive clinics were held for the prevention and correction of diastolic errors and minor ailments, at these there had been 32,611 attendances, as compared with 28,978 in the preceding year. Certain special investigations had been performed including the study of strains of hæmolytic streptococci from cases of scarlatina with reference to their toxic and immunological properties. Streptococci of both scarlatinal and non-scarlatinal origins had been found to possess toxic properties. The necessity for examining the throats of persons attending obstetrical cases complicated by puerperal infection was brought out by the results of examining attendants in a lying-in institution where four cases of puerperal fever had occurred. One nurse was notified as suffering from erysipelas, several other nurses developed cases of sore throat and on taking throat swabs from 54 persons on the staff of the hospital 15 or 27 per cent were found to give positive results as regards hæmolytic streptococci. A large number of tests were made in regard to the virulence of different strains of the diphtheria bacillus. It was found that the intracutaneous test was more satisfactory than subcutaneous administration.

Small-pox Outbreak in Scotland

An outbreak of small-pox of mild type has been reported by the medical officer of health for Arbroath, some dozen cases having so far been traced. Another case, which appears to have been infected in Brechin, has been found in an institution. As chicken-pox is at present notifiable in Scotland, and as the cases of small-pox so far reported have been mild, it is possible that cases of the latter disease may be mistaken for chicken-pox, so that practitioners are requested by the Scottish Board of Health to scrutinize carefully all chicken-pox notifications, and in doubtful cases to request investigation by the local medical officer of health. The Board is prepared to supply local authorities with vaccine lymph at the cost price of 3d per dose.

Edinburgh Veterinary College

At the annual distribution of prizes at the Royal (Dick) Veterinary College, Edinburgh, on June 27th, Sir Thomas Hudson Beare, chairman of the board of managers, who presided, remarked that it was particularly gratifying that the number of post-graduate students remained large. It was hoped to develop post-graduate teaching and research more and more each year. The board of management would gladly strengthen its teaching staff if more money became available. Lord Novar, who distributed the prizes, said that veterinary science, thanks largely to the Royal Veterinary College, had made great progress in the last half century. The old-time veterinary practitioner, like his contemporary the old Highland houndsman, was a great personage and often did good work, thanks to his individual experience, character, and popularity. The transition period to the new style had been rather an anxious

one for the stock owner, and agriculturists sometimes regarded the half-trained veterinary surgeon with some trepidation. The human bond between the patient and his medical adviser was one of the closest known, and a similar bond should exist between the stock owner and the veterinary surgeon. Lord Novar believed that there was a great future for veterinary practice, because in Great Britain they possessed the finest stock in the world. A great deal depended upon research, and the speaker suggested that in this respect some inherent qualifications were essential. The college was, however, entitled to support, and he hoped that agriculturists would subscribe more liberally to it when they could do so. He suggested also that county councils would find the college worthy of financial support.

Memorial to the Late Dr J W Allan

A tablet, erected by former colleagues of the late Dr James Watson Allan to perpetuate his memory, was unveiled on June 26th in the Belvidere Local Hospital, Glasgow, of which he was physician superintendent for many years. An account of his career was published in the *Journal* of February 21st, 1925. In handing over the tablet an appreciative address was given by Dr A K Chalmers, formerly medical officer of health for Glasgow, who said they had met to place on permanent record a tribute to the bond of friendship and affection which had grown up between one of the early superintendents of Belvidere and those whose privilege it was to serve with him. The special significance of their meeting was in this, that although Dr Allan was with them until three years ago, it was more than half a century since he was appointed physician superintendent at Belvidere, and fully a generation had passed since he resigned office. Yet the influence which radiated from him still lived. He was appointed in 1875 and resigned in 1893, and during these eighteen years a succession of residents not only reaped a rich harvest from the wealth of his clinical experience, but came to regard him with an almost filial devotion. In all there were fifty-four residents during this period. Many of them had already completed their tale of years, and the others were widely scattered. Some had gone to the ends of the earth—Africa, India, Australia, and China had claimed some many were in England about a dozen only were in Scotland and still fewer were in, or near, Glasgow. Discussing the nature of Dr Allan's influence, Dr Chalmers said that residents saw, on the one hand, strenuous effort to reach a high standard of efficiency in the ward work, and on the other a studied consideration for their social comfort. The speaker then recalled the position of the hospitals fifty years ago, and spoke of the part played by Dr Allan in gaining public confidence in those institutions and in promoting the education and training of nurses. When Dr Allan left Belvidere, he said, the hospital was established in the confidence of the public, and its reputation had already extended far beyond the boundaries of the city of Glasgow. The dominant note in his character was sympathy—sympathy with the patients and with the anxiety of their friends, and sympathy with the nurses and the demands on their patience. Dr Chalmers concluded by asking the Health Committee to accept the tablet from the residents of Dr Allan's time as an expression of their affectionate remembrance of one who did so much to establish Belvidere in the public confidence and esteem.

Conference of Sanitary Inspectors

The thirty-fifth annual conference of the Sanitary Inspectors' Association of Scotland was held at Dunfermline on July 6th. Mr Archibald Englesim, public health department, Paisley, in his presidential address said that it was desirable that sanitary inspectors in larger centres should hold a diploma from a university, but there was no opening for such specialists in the smaller burghs. Dr Dittmar, Chief Medical Officer, Scottish Board of Health, remarked that the sanitary inspector nowadays had to know something about buildings, building construction, meat inspection, and dairy work, so that he must be a man of fairly wide training. Some educational scheme on the lines of that provided for arted pupils in the engineering trade

would have to be devised, with a combination of theoretical teaching and practical experience. He thought that if a course like this were worked out the status of the sanitary inspector would take care of itself.

England and Wales.

Presentation to Sir George Makins

On June 20th, in the Governors' Hall at St. Thomas's Hospital, Sir George Makins, GCMG, CB, was presented with his portrait, the gift of his old friends, pupils, and colleagues. The painting is the work of Mr. James S. Sleator, and was much admired. The proceedings, which were quite informal, were opened by Sir Arthur Stanley, treasurer of the hospital, with a few warmly appreciative words on behalf of the governors. He was followed by Sir Percy Sargent, Sir Cuthbert Wallace, and Dr. H. G. Turner, who, as friends and colleagues of different periods, dwelt in turn on the length and value of Sir George's services to the medical school and hospital, and on the affectionate regard in which he was held by all with whom he was associated. Special reference was made to Lady Makins, who had taken so large a share in establishing and maintaining these kindly relations. Sir George Makins, in reply, expressed his profound appreciation of the honour done to him. He was deeply touched by what the various speakers had said, and he proffered his sincerest thanks to his many friends for the gift of his portrait, which in the fullness of time would become the property of the hospital.

London Hospitals and the Middle Class

The report of the Pay Bed Committee of King Edward's Hospital Fund for London on hospital accommodation for the professional and middle classes will, it is understood, be issued shortly. According to a forecast of the committee's findings, which has gained general acceptance, the report suggests the allocation of beds in all the large London hospitals for persons who, while they cannot afford to meet the normal specialist fees and private nursing home charges, can make a fixed weekly payment for hospital treatment. Proposals for the initiation of a voluntary insurance scheme for this class are believed to have found favour in the eyes of the committee. It is suggested that each person entering the scheme should make an initial payment of £10, so providing funds which could be used to extend pay-bed accommodation. An annual payment of £2 16s. would also be required, and, while this alone would confer a title to participation in the benefits of the scheme, those who made initial payments would secure a measure of preferential treatment. Lord Riddell, president of the Royal Free Hospital, commenting on the proposal outlined above, has said that the provision of beds was the main problem, and that cheap paying beds were needed not only in the big central hospitals, but in the suburbs and outlying districts. The best arrangement, in his belief, would be the provision of paying beds at the various local hospitals, giving the patients' doctors access to them.

Blackburn Royal Infirmary Extensions

A new wing at the Blackburn and East Lancashire Royal Infirmary, erected as the main feature of the town's war memorial scheme, was opened on June 16th by Mrs. R. A. Yerbrough. The extension scheme, which has involved an expenditure of about £95,000, was prepared by Dr. D. J. Mackintosh, medical superintendent of the Western Infirmary, Glasgow, in conjunction with the local architects. It provides accommodation for ninety beds in five wards, together with two operating theatres, new administrative offices, quarters for the resident medical staff, and a section which will be used to house members of the nursing staff until the extension of the existing nurses' home is possible. The War Memorial Wing, as it is to be called, consists of an octagonal central building, connecting the two new ward blocks, and having in front of it a two-story block for the administrative offices and operating theatres. Covered corridors connect the extension to the older building. In the new wing, on the ground floor, the

west block contains the children's department, and the east block the medical staff quarters. On the first and second floors, in both blocks, there are wards of sixteen beds each and small two-bed wards, together with the usual ancillary accommodation, all four large wards have open sun balconies on the south side. The third floor contains bedrooms for the domestic staff, those in one block being occupied meantime by members of the nursing staff. Over the porte cochère at the entrance is a corridor linking the operating theatres with the central part of the new wing. Special attention has been given throughout to the equipment of the building, and notably to heating, lighting, and ventilation. At the opening ceremony the mayor of Blackburn, Mr. J. A. Ormerod, announced that £101,632 had been contributed to the War Memorial Fund, and stated that this had sufficed to cover the cost of building and furnishing the War Memorial Wing and also of erecting a memorial monument elsewhere in the town. As a result of the extension the board of management has carried out a supplementary scheme at a cost of about £50,000, a new laundry, boiler-house, mortuary and post-mortem room have been provided, and extensive additions have been made to the kitchens. A large x-ray, electrical, and massage department, including an orthopaedic gymnasium, has been erected. It is proposed, in the near future to extend the nurses' home and to enlarge the out-patient waiting hall and casualty department.

Medical Supervision of Children

The London County Council resolved recently, on the motion of Dr. Stella Churchill, to ask its Education and Public Health Committees to consider and report as to the advisability of unification of the medical supervision of school and other children in London in order to obtain continuity of medical work throughout child life. The two committees concerned have met and have heard the views of Dr. Churchill, who has stated that what she had in mind was medical supervision alike of children of school age and of pre-school age. Instructions have been given for a report to be prepared on the subject, dealing with it from the broader aspect of the best method of bringing into relation with one another, and securing co-operation between, the school medical service and the services responsible for the welfare of children of pre-school age. The committees are to report as soon as possible after the summer recess.

Wholesale Dairy Organization

The opening of what is claimed to be the largest and most modern wholesale milk depot in the world, that of the London Wholesale Dairies, Limited, at Vauxhall, was celebrated by a luncheon on July 6th, presided over by the Hon. Sir Arthur Stanley, and attended by the mayors of Lambeth and Deptford and by a number of London medical officers of health, one of whom, Dr. Charles Porter of Marblebone, spoke to the principal toast. The guests were taken round this remarkable building, and were impressed by the absolute cleanliness and efficiency of the handling—an unfortunate word, because the process is a rather extreme example of mechanization—of the thousands of gallons of milk which pass every day through this depot on its way from the farmer to the retail dairyman. The visitors were taken to the pasteurizing floor, where the milk is heated to 145° F., and held at that temperature for thirty minutes. In the bottle and churn room they watched the filling process, which takes place entirely by machinery, and is so arranged that the filling begins the moment the sterilization of the vessels is completed. In the sterilizing room the milk was shown being sterilized in the bottle under pressure. An interesting feature of the plant is the huge glass-lined holding tanks, which have no crevices or corners, and thus lend themselves to easy cleansing, also the "homogenizers," machines which exert a pressure of 3,000 lb. to the square inch and break up the fat cells in the milk so that the cream does not separate and a uniform product in the finished sterilized milk is ensured. It was stated that samples of milk are taken for laboratory control every half-hour throughout the entire process. The visitors also noted the provision of baths and wash-rooms for the employees, and the excellent lighting and ventilation of a modern hygienic factory.

Correspondence.

DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL

Sir,—In a letter from Dr Bone and Dr Le Fleming, appearing in your issue of July 7th it was pointed out that as the university, professional, and consulting element is so fully in evidence on the General Medical Council it is fitting that the direct representatives of the profession should be general practitioners. With this I am absolutely in accord.

At a meeting of the profession in my Division (Kensington) it was resolved to put forward my name as a candidate for nomination at the coming election. I am, and have been for the whole of my professional career, a general practitioner pure and simple. I served for five years on the General Medical Council as a direct representative, and therefore am thoroughly conversant with its methods and procedure, so that if I were elected I could at once take my place in its deliberations without having to serve any apprenticeship.

In the British Medical Association I have held every possible office except that of Chairman of Council and Treasurer, having been Chairman of my Division, President of my Branch, member of the General Council for seventeen years, Chairman of the Representative Body, 1915-18, Chairman of the Medico-Political Committee for seven years, President of a Section at the General Meeting, 1920, member chairman, and vice-chairman of numerous special and ad hoc committees, and have also represented the Association on many outside bodies, in some cases for many years. During the whole of this time, both within the B.M.A. and also very largely as a member of outside councils, I have done my utmost to further the honour and best interests of my profession. For these reasons I have allowed my name to go forward as a candidate, and I appeal to all members of the profession for their support. Should I be re-elected I should do my very best to carry out the duties of the post, as I did when I was a member some years ago, when I never missed a single session or sitting of the Council.—I am, etc.,

London W 2, July 7th

I. B. TURNER

Sir,—At the request of a meeting of the practitioners of Leicestershire and Rutland I have agreed to submit myself as a candidate for the General Medical Council. I am in entire agreement with Drs Bone and Le Fleming that it is essential to secure the election of those who have a thorough acquaintance with the problems and difficulties of the general practitioner, an acquaintance which I believe I possess.

As Honorary Secretary for nearly twenty years of a Division which is composed almost equally of industrial and rural constituents, as Chairman for fourteen years of the Leicester Panel Committee, as the promoter of the largest public medical service in the country, and now the President of the Leicester section, I have been in close touch locally with every form of medical practice, while as Chairman of the Representative Body of the British Medical Association and a member of all its standing committees, either in the past or at the present time, I have been actively engaged for many years in central work on behalf of the profession.

On these grounds I venture to invite the support of the profession as a whole.—I am, etc.,

Leicester July 9th

R. WALLACE HENRY

Sir,—In the current issue of the *British Medical Journal* I notice there is a letter, dated June 27th, giving the experience of, and asking for support for, two practitioners who are candidates for the election in October to the General Medical Council.

In consequence of that appeal, I venture to state that I also have been nominated unanimously by a meeting of

the profession here, called by the local Division. If the accompanying list of my experiences and appointments, past and present, is not too long I should be greatly obliged if you will be good enough to insert it in your next issue and so to give voters, whom I cannot reach in any other way, information that will show I have had administrative and other experience which might be useful on the General Medical Council.

I do not make any promises, beyond that of a faithful attention to the honour and interests of the profession (which really are those of the community), as the duties of the General Medical Council are limited to the carrying out of the Medical Acts, so far as they concern medical education and registration.—I am, etc.,

C. H. MILBURN

Harrogate July 9th.

* A summary of Dr Milburn's experience in public and medico-political work will be found in the *Supplement* this week at page 18, together with details relating to the other candidates who have been nominated at meetings of the profession convened by Divisions of the British Medical Association.

VOLUNTARY HOSPITALS AND THE STATE

Sir,—On the agenda paper of the last meeting of the Marylebone Division there appeared the cryptic word "Amendment by Dr Graham Little, M.P.," and a copy of this paper was sent to the 669 members of the British Medical Association in the Marylebone Division, not, as Dr Little would have us believe, to 1,500 medical practitioners.

The whole Division became astir on receipt of the agenda, but so content, apparently, are the members of the British Medical Association in this large and influential Division with the Report of the Council, including the well thought-out Appendix VII, that only eleven thought it worth while to attend in order to become acquainted with the terms of this secret amendment. One of these was a close follower of the proposer, who in due course seconded the amendment, but in terms which brought strong condemnation from a stalwart of the Division.

The amendment was so amazing in its wording that no one could be surprised—not even Dr Little himself—at the deserved defeat it sustained.

In his letter printed in your issue of July 7th (p. 34) Dr Little states that the italics were his own in his extract from the scheme to be put before the Representative Body. Unfortunately, his italics, and perhaps intentionally, miss the essential word in the extract. Here I reproduce the extract with italics which are my own.

The first step in the attempt to co-ordinate the work of the voluntary and municipal hospitals must be the establishment of a central *advisory* authority appointed by the Minister of Health.

The Council in adopting this portion of the carefully thought-out scheme of the Hospitals Committee for the co-ordination of hospital provision did so fully aware that the words implied

- 1 That a central advisory authority was essential
- 2 That this body had to be central but only *advisory*
- 3 That such a body could be called into existence only by the Minister of Health himself

Being solely advisory in function this body could not possibly lead to the inevitable transfer of the *control* (again the italics are mine) of the voluntary hospitals to the State as represented by the Ministry of Health. Sir Thomas Horder, in his statesmanlike address to the British Hospitals Association Conference, puts the matter in a nutshell when he says, "I think this is a boggy. I find it impossible to believe that any statesman can sincerely consider such a step" (*British Medical Journal*, July 7th, p. 27). With this statement I am in entire agreement, and so I believe will be the majority of those astute persons who will make up the Representative Body at Cardiff.—I am, etc.,

W. McADAM LECHE

B.M.A. House July 9th

Chairman of the Hospitals Committee

Sir,—The recent conference of the British Hospitals Association at Southport does not seem to have received as much notice in the press as its chief subject-matter deserved. That matter was the part the voluntary hospital system should take in the forthcoming arrangements for the public health services of the country.

Sir Thomas Horder's address¹ brought out clearly and strikingly the value of the voluntary system in the production of a body of well-trained medical men, and it showed how their training might be made still more valuable if to the resources of the voluntary hospitals those of the Poor Law institutions should be added. It was, however, of cardinal importance that the principles underlying the voluntary system should be maintained, and the activities of the Association might be very usefully employed in the consideration of means to this end. In the debate that followed different possibilities were considered. The optimistic thought that the two greatest assets of the system were the affection of the patients for the voluntary hospitals, and the interest taken in them by their supporters. The doubting averred that both these classes of the community were inarticulate, and that the first sign of dissatisfaction on the part of the supporter might be the withdrawal of his support. The debate ended on a note of hope—not over sanguine—that it might be possible for two bodies to work in co-operation, one managing the voluntary, the other the municipal hospitals.

To many it will occur that the fulfilment of this hope could only furnish another instance of the lamb lying down beside the lion: voluntary control would soon be engulfed, and voluntary support would promptly disappear. Thus, fortunately, is not the end desired by the Minister of Health, who has expressed himself emphatically in favour of the retention of the voluntary system. But it was indicated at the conference that he may find arrayed against him forces of a formidable nature. For instance, a large number of the younger medical men who would be required to serve the transformed Poor Law institutions, and in consequence those also now on the staff of the voluntary hospitals, might strongly favour State or municipal control as connoting remuneration for their services. The spirit which animated their elders to accept honorary posts, and wait for the rewards that come in later life, would fade to vanishing point when faced with the opportunity of making at once a substantial income as a set-off against the much heavier expenses and costlier way of life of a young consultant of the present day. Whatever justice there might be in this claim the real problem would be, Could the country, at a time when economy is so vitally needed, stand the large additional expense?

Another opposing force anticipated at the conference was the abiding influence of the permanent officials of the State and municipal departments. Could such a fellow as the voluntary hospital be stabled with the municipal institution accustomed to a liberal diet of red tape? A disquieting prospect for the municipal eye. Moreover, it was thought possible that a vast additional outlay might be involved in specious but ill-considered projects. What opportunities there would be in the costly equipment of modern hospitals! It has been suggested by an eminent municipal officer that under the new regime the voluntary hospitals would necessarily come under the control of the London County Council. As evidence of the capacity of the Council to assume control of large undertakings their management of education and housing were instanced. Many think there is plenty of room for criticism in their expenditure on the former. Becontree does not exactly support the testimony of the latter. It will not be forgotten, either, that the patient Londoner has to make good annually a deficit of some £250,000 on his trams.

The time would seem to be ripe for the representatives of the London hospitals to devise a scheme under which the voluntary and municipal institutions could work together without the loss of the voluntary management and support. The representatives of the Scottish hospitals have been in communication with the Secretary of State for Scotland in regard to this matter, and they have been asked to form a committee and frame their suggestions. It might be of

appreciable assistance to the Minister of Health if the London hospitals would become articulate by adopting a similar course—We are, etc.,

LONDON HERRY,
President
FREDERICK ELFY,
Chairman of Council
R. ROY WILSON,
Chairman of Weekly Board

Chelsea Hospital for Women July 9th

ARSENIC AND THE REALM OF UNCERTAINTY

Sir,—The problem of arsenical poisoning is intimate y bound up with certain problems of the circulation, and in particular with the circulation in the liver. In the *British Medical Journal* of December 17th, 1927 (p. 1137), a method of direct observation of the circulation in the liver in the toad was detailed by me, and in addenda published privately the existence of very considerable stasis in the liver sinusoids was discussed. The possibility of the influence of respiratory compression of the liver as a determining factor in ensuring a flow of blood in all the liver sinusoids was foreshadowed, and recent research by Professor Leonard Hill (see forthcoming paper in the *British Journal of Experimental Pathology*), wherein he notes that, no matter how careful manipulation may be, in toads profound stasis exists, lends him to state that respiratory movements are essential, and, of course, muscular movement of the body generally. The heart alone cannot ensure a complete circulation of the liver, but needs to be aided by respiratory and muscular movements. Consequently, in disease it is imperative that we look for evidence of liver stasis.

The problem of shock involves the problem of the disappearance of blood from active circulation. Professor Cannon considered that blood might be dammed back in the portal circulation by constriction of the hepatic radicles of the portal vein, but it is obvious in shock, with general muscular passivity and with very feeble breathing and diminished arterial blood pressure, that all the factors are present which would produce the stasis of the liver seen under the microscope by L. Hill and by myself. Now as the amount of blood normally circulating in the liver is a large fraction of the total blood—rather more than a quarter—stasis in the liver would throw out of circulation blood than can ill be spared. Further, in certain forms of heart disease (paroxysmal tachycardia) the liver may swell considerably and quickly subside on restoration of normal cardiac rhythm. Hence one can say, as the liver swells, more blood flows into the liver than flows out, and the extra blood in the liver is either stasied in the sinusoids or the total mass must be moving very slowly.

In the case of arsenical poisoning the condition of cloudy swelling of the liver cells must increase resistance to blood flow, and as the blood pressure of the portal vein is roughly 10 mm. of Hg, any extra resistance to the passage of the blood must lead to stasis. L. Hill has measured the blood pressure in the liver sinusoids where blood is moving and found the blood pressure about 2 mm. of Hg. In arsenical poisoning a so-called fatty degeneration of the liver exists. The evidence from phosphorus poisoning leads one to believe that the fat deposited in the liver is really carried to the liver from the fat depots of the body, and that the protein of the liver cell is not transformed into fat. The carriage of this fat is also a problem of the circulation, and if it be the case that the liver microphages engulf fat, the existence of stasis of blood flow in liver sinusoids will influence such removal of fat from the blood stream.

We are now in a position to consider something in the realm of uncertainty and arsenic. In the case of R. v. Maybrick, Professor Tidy objected to an estimation of the total quantity of arsenic in the liver being based on an estimation in a part of the liver only. In other words, if the arsenic present in, say, one-third of the liver in one piece was determined, Professor Tidy maintained that multiplying the amount found by the appropriate factor would not necessarily give a correct amount for the whole liver. In other words, arsenic was found by him to be

¹ *British Medical Journal* July 7th, p. 27

differently distributed in amount in different portions of the same liver. The reason for this discovery may be (1) unequal penetration of the cells of the liver by arsenic, (2) unequal eliminating power of the cells of the liver for arsenic, (3) unequal distribution of blood flow (carrying arsenic) to different portions of the liver (4) unequal carriage of arsenic away from the liver owing to unequal distribution of blood flow to portions of the liver. As regards (1) and (2) it is difficult to see how peculiarities of individual cells would not cancel themselves out in the vast number of cells that must be in a portion of the liver. We are left then with (3) and (4), which could be accounted for by stasis in the liver. If this be granted it is well that one should note the consequent bearing on the medico-legal question of the quantity of arsenic found in the body in different cases of proved arsenical poisoning.

If one is going to argue from quantities of arsenic in the liver and in other organs of the body, say heart and kidney, in different cases one ought to be sure that the poisoning cases compared were *alike* in the existence or non-existence of stasis in the liver. And such knowledge is not in the realm of certainty, but in the realm of uncertainty. The symptoms of arsenical poisoning, the peripheral neuritis leading to a partial or more or less complete paralysis of the limbs—it may be also paralysis of the intercostal muscles leading to immobility—would favour stasis. Vomiting and straining might lead to removal of stasis for the time taken by the muscular acts to be performed, to relapse once more into immobility. It seems fair, too from the descriptions given in R. A. Armstrong, and other cases, to conclude that terminally at least, shock phenomena are present and shock leads to stasis. Further, the rapidity of the heart's action due no doubt to weakening of the heart by the poison, is also to be expected where the total volume of the circulating blood is diminished either by haemorrhage or by stasis.

In the case of R. A. Seddon as pointed out by Sir William Willcox¹ the amount found in the liver was 0.17 gram, while 1.03 grams were found in the muscles. Sir William Willcox states that this distribution of arsenic was probably "owing to there having been a break in the repeated dosage." But it might be just as well argued that the relatively low figure of 0.17 gram in the liver was due to the absence of stasis in the liver, or that the stasis in the liver occurred after the liver had been largely depleted of arsenic, while the high figure of arsenic found in the muscles over 1 gram was due to increased muscular activity during spasms of writhing, vomiting and straining, because the researches of Krogh etc. have revealed the great increase of capillary blood flow in the muscles during activity. Muscular activity would assist the circulation in the liver thereby depleting it of arsenic and muscular activity would tend to arsenic penetrating the muscle cells though increased muscular capillary bed.

I pass now to the question of the quantity of arsenic found after death in the stomach and intestinal tract. In the very valuable paper by Sir William Willcox tables are given of quantities found in various cases. But I do not find in this paper or in the new edition of Taylor's *Medical Jurisprudence*, any help in solving this problem. When arsenic is taken into the system it is absorbed and carried to the liver in the first instance by the portal circulation. Some of the arsenic remains in the liver depending in great part on the circulatory conditions, and above all on the absence or presence of stasis. But some of the arsenic in the liver will be re-excreted along the stomach and intestinal tract and in none of the analyses I have read do I find any attempt made to state how much of the arsenic found in the contents of the stomach and intestines was excreted arsenic from the liver, and not a portion of the arsenic originally taken which remained in the stomach or bowels. Further, there seems to be no attempt made to settle whether the arsenic in the intestinal tract, *excluding the contents* was arsenic that had been absorbed on its way to the liver or arsenic that was in process of excretion from the liver.

I do not say these problems can be solved, but one is bound to consider them before applying a gastro-intestinal

time-table. By that I mean calculating the time when a dose of arsenic was taken by the distribution of the arsenic in the stomach and bowels. How does one know that cases may not crop up where the whole of the arsenic in the stomach and intestinal tract was arsenic excreted from the liver, and if stasis may be present in the liver, how long has that arsenic before excretion been lying there? Yet on the question of the time of a dose may depend a verdict—I am, etc.,

Halesowen July 7th

JAMES M. McQUEEN

GASTRIC SECRETION OF NEUTRAL CHLORIDE

SIR,—In his letter which you published on June 30th (p. 1128) Dr. I. S. Hansman writes to defend a paper by himself and his colleagues against some criticism said to be contained in a letter from me in the *British Medical Journal* of March 24th (p. 521). As Dr. Hansman writes from Australia I am anxious to say nothing of a controversial nature, and would indeed prefer to say nothing at all, but as silence is sometimes more dangerous than speech I would like to point out that the letter he refers to was written in reply to one from Dr. Ponton, and that from beginning to end it contained no word of criticism of the work of Dr. Hansman and his colleagues, and I am quite at a loss to know where he can possibly have found it. I merely stated the main conclusions at which they had arrived and contrasted them with those of Baird, Campbell, and Hern in order to show that the two sets of authorities were diametrically opposed in their views as to the origin of the gastric neutral chloride, and that they could not therefore be cited together as witnesses on the same side. I added no critical comment of my own on either paper. I am sorry if in giving Dr. Hansman's conclusions I unwittingly made much of his statement that the chloride passed through the stomach wall, I admired the restraint that led him to claim no more than his evidence warranted and therefore I purposely used his own phraseology.

Dr. Hansman's last paragraph has really no connexion with anything I wrote. I have never questioned the accuracy of his mathematics. What I do question in my own mind is the accuracy of the data on which his calculations are based. I do not accept his assumptions on the chloride content of the duodenal contents, and his simple little sum of $1+1$ represents itself to me as $1+x$ where x is the sum of various unknowns. Controversy on this point is useless and for that reason I have carefully refrained from it. The question can only be settled by further experiment—I am, etc.,

London S.W. July 4th.

G. W. GOODHART

ADRENALIN IN MEDICAL AND SURGICAL PRACTICE

SIR—Mr. W. M. Beaumont, in his article of June 30th (p. 1104) gave a list of conditions in which adrenaline mydriasis occurs when this substance is instilled into the conjunctival sac. He omitted the important group of patients who give this reaction at the time of the menopause, a condition which I have shown in this *Journal*¹ and elsewhere² is associated with a general increase in the tone of the sympathetic nervous system.

In my latest publication on this subject³ I showed that

- (1) Women at the menopause who complain of flushing display an increased sensitiveness to adrenaline.
- (2) This increased sensitiveness is manifested as certain atypical phenomena associated with intravenous and subcutaneous injections of adrenaline, and its instillation into the conjunctival sac.
- (3) Whereas these atypical phenomena occur in all cases of association of the menopause with flushing, adrenaline mydriasis is present only in cases complaining of severe flushing.
- (4) The atypical adrenaline phenomena do not occur in

¹ *British Medical Journal* 1927 ii 14-15.

² *The Flushings of the Menopause*. Ballière, Tindall and Cox 1927.

³ *Endocrinology* January-February 1928 pp. 59-64.

those women at the menopause who do not complain of flushing nor in women whose menstrual cycles are normal.

(5) Adrenaline sensitiveness at the menopause associated with flushing disappears when the attacks of flushing cease—I am, etc.,

London, W 1, June 29th.

JOHN H. HANNAH, M.D.

THE PAPILLAE FOLIATAE AND CARCINOPHOBIA

SIR,—I was much interested in the memorandum entitled "The papillae foliatae and carcinophobia" by Mr. C. Jennings Marshall in your issue of July 7th (p. 13). I have frequently come across the condition he describes, and have found it to be almost invariably bilateral and to occur only in adults. I had previously regarded it as an hypertrophied, inflamed, or oedematous condition of one of the laterally placed papillae villatae of the tongue, but will in future look more closely into its site of origin—I am, etc.,

F. COLEMAN, M.C., M.R.C.S., L.D.S.,
Dental Surgeon St Bartholomew's Hospital

July 10th.

ANAESTHETICS AND DIABETES

SIR,—In his letter in the *Journal* of June 30th (p. 1127) Dr. S. Levy-Simpson does not mention a most suitable gas anaesthetic for diabetic cases—namely, ethylene. The late Dr. S. R. Wilson of Manchester, in his book *Outlines of Anaesthesia*, describes this gas as specially valuable, inasmuch as any operation can be performed on a person who is anaesthetized with it. The only danger is asphyxia, which is easily avoided by using sufficient oxygen. Dr. Wilson says:

In my experience after-effects are extremely rare and the gas in this respect is very similar to nitrous oxide. One or two subjects had a feeling of nausea and no vomiting. Its greatest value is in bad risk anaesthetics when nitrous gas is insufficient or undesirable owing to associated anaemia and ether is considered detrimental to tissues already damaged.

Dr. Wesley Bourne, in a paper read before the joint meeting of the Canadian Medical Association, the Ontario Medical Association, and the Canadian Society of Anaesthetists on June 17th, 1927, quotes a series of tests proving that ethylene has no deleterious effect on the body cells generally, and especially the liver. According to similar tests ether, chloroform, and ethyl chloride had considerable detrimental result.

I think it is generally admitted that diabetic patients have reduced carbohydrate tolerance after anaesthetization with these substances.

In days gone by, before the introduction of insulin, diabetes was often treated with opium, and, in my own experience, with very good results, especially in the case of patients over the age of 50. Therefore my suggestion for an ideal anaesthetic for a diabetic would be a fair dose of opium or morphine one hour before operation and then a nitrous oxide and oxygen gas anaesthetic. Almost any operation can be done with this, and it is very satisfactory to both the surgeon and patient.

I have just returned from a visit to the United States and Canada, where I saw gas and oxygen given for nearly every operation imaginable, and many surgeons did extensive operations with no other anaesthetic—I am, etc.,

Doncaster July 2nd.

E. J. CHAMBERS

SIR,—In reply to your correspondent in the *Journal* of June 30th (p. 1127) the quotation from my paper, as so often happens, is incomplete. Removed from its context, the sentence is liable to convey an erroneous impression.

I would point out that my opinion of ether as a satisfactory anaesthetic in diabetes has only been proved after treating these cases (which are always productive of grave anxiety) with great care. With the exception of the acute urgencies, all cases have been carefully prepared and rendered sugar-free before operation. During this time and for a week afterwards blood sugars have been estimated at least four times daily, in order to secure adequate control. And further, in my service, no case is allowed to be operated upon unless 50 grams of glucose

and an adequate insulin dose have been administered half an hour before anaesthetization.

Apart from such routine care, I have no knowledge of anaesthesia in diabetes, but I would repeat that under these conditions ether is a satisfactory and a safe anaesthetic as regards both the immediate and remote results—I am, etc.,

Manchester, July 6th

G. J. LANGLEY

EXPERIMENTS ON ANIMALS

SIR,—May I congratulate you on your article on the above subject in the *British Medical Journal* of June 30th (p. 1119). Its moderation and good sense are to be commended, and I should like to suggest that you might see your way to go a little further in bringing about a better feeling in the mind of the general public.

There is no doubt that there is a certain uneasiness at the vast increase in animal experiments, and the average layman does not realize that the great majority of "experiments" are painless. It is realized, however, that, looking at physiology from an international standpoint (and after all the physiologists of different countries are largely working together), a great amount of prolonged and unnecessary pain is inflicted on animals, owing either to anaesthetics not being compulsory in cutting experiments in certain countries or to the existing law not being properly administered. If the defenders of research could use their influence to interest the League of Nations in this international question, and aim at purging the science of physiology from all reproach, what an advance in humanity it would be!

The British are renowned for their kindness to animals. Surely British physiologists would have no objection to helping to free their science from the reproach under which it at present labours—I am, etc.,

Bridgwater July 2nd

HAROLD PARSONS, M.B. Camb.

MIDWIFERY MORTALITY

SIR,—In your issue of June 30th (p. 1126) Dr. David Roxburgh submits some remarkable observations for—as he puts it—"the consideration of your readers." He actually laments the passing of the "ignorant and untrained woman" who acted in the capacity of nurse, and deplores the "shortsightedness and stupidity" of certain doctors who helped to bring the Midwives Act into being. He admits that these untrained women "did nothing" did not attempt to do anything. That is quite true. Most of us have suffered from them. They "did nothing" so frequently that when the unfortunate doctor was at last called in he often could do little or nothing either. That was one of the reasons why they were abolished.

I may have mistaken the intention of Dr. Roxburgh's letter, but surely he is not suggesting that these women should be reinstated, even though it might be to the advantage of the young doctor who needs more experience in obstetrics. Presumably these "untrained and ignorant" midwives were abolished in consequence of the high rate of mortality and puerperal sepsis that were so rampant in those days. I would ask Dr. Roxburgh a plain question. Which would he prefer to see at the bedside of one of his own midwifery cases—a clean, smart, up-to-date, efficient, well-trained licensed midwife, or some old body whose only qualification for the job was, in her own words, "Cos I've bin a mother of ten meself, so I knows what 'er's going through"? And if a properly trained nurse-midwife is available nowadays for the richer classes surely her services are needed still more for those who are less fortunate in their financial resources.

I agree with Dr. Roxburgh that the average young newly qualified doctor is but ill equipped in knowledge and experience when he is called upon to tackle a difficult confinement. I trust that I do not come under this category, for I have personally attended, I suppose, at least the 1,000 cases which he considers are necessary to make a man efficient. But the recently qualified man's inexperience is not caused by the Midwives Act. It is due, and always has been to the inadequate obstetric training

which he undergoes at his medical school. A minimum of twenty cases in order to get "signed up" is far too small a number, and even if, during these twenty cases, a difficult one crops up, he always has the hospital obstetric medical officer at his back who will do the work for him. It is true that when he stunts general practice in earnest, he can learn a very great deal by nitenatal methods, even though he may not be called upon to attend a large number of confinements, but this does not excuse his medical school for giving him so poor a start.

As a matter of fact, judging from the advertisements for the sale of medical practices, the average general practitioner wants to do as little midwifery as he possibly can. In the advertisements, phrases such as these constantly occur: "midwifery not encouraged," "no midwifery." And apparently they are inserted as an inducement to buy. The general practitioner of today seems only too pleased to leave all, or as many confinements as possible, to the well-trained and efficient licensed midwife.

Thank Heaven the "untrained and ignorant women" have passed out of existence for ever, and I, for one, never wish to see their like again—I am, etc.,

JOHN READ POOLER M.B., Ch.B.

Newport Shropshire July 2nd

HAEMATURIA AND INSULIN ADMINISTRATION

Sir,—In your issue of June 9th (p. 977) Drs. R. D. Lawrence and A. S. Hollins drew attention to the occurrence of haematuria during the administration of insulin in diabetes. In view of the rarity of the condition the following two cases would seem worth recording.

Case 1—This patient, a boy aged 3 years, had severe diabetes in May 1925 when he was 2 years old. He had been sugar free with dieting and with 12 units of insulin twice daily until May 5th, 1926, when he contracted scarlet fever. Temperature 100° F., vomiting and a marked rash. Tonsils much injected and tonsillar glands enlarged and tender. Urine sp. gr. 1030 sugar plus. Rothera very marked, no albumin. Drowsy. May 6th semi-conscious vomited once temperature 99° F. given insulin 12 units twice urine as before no albumin volume 30 oz. in twenty-four hours. May 7th condition the same temperature 99° F. insulin 12 units twice urine 25 oz. sp. gr. 1032 sugar plus. Rothera very marked, a thick cloud of albumin smoky colour many red blood cells but no casts seen. May 8th frequent vomiting comatose. In spite of large doses of insulin with glucose and alkali per rectum he became completely anuric and died the following day. A necropsy was not obtained.

The chief points in this case are that nephritis does not commonly occur so early in the course of scarlet fever, haematuria appeared at a time when only comparatively small doses of insulin were being given, and a marked ketonuria was present without albuminuria before the haematuria developed.

Case 2—A boy aged 10 years came under treatment for thirst and weakness of the legs on January 26th 1928. These symptoms had then been present for one month. Urine volume 40 oz. sp. gr. 1032, neutral much sugar acetone and aceto-acetic acid plus no albumin. He was drowsy but could easily be roused. The temperature was normal and remained so throughout. The tonsils were normal and the tonsillar glands were neither enlarged nor tender. There was no obvious source of local sepsis and there was no history of any recent sepsis or acute infectious. Several teeth were carious and were later extracted without any general reaction. There was no obvious pyorrhoea or gingivitis. On January 27th he became comatose the blood sugar then being 0.476 per cent. He was given five doses of 20 units of insulin and in the morning of the 28th two more doses with 20 grams of glucose. He made a rapid recovery from the coma and thereafter felt quite well. During the day he passed 41 oz. of bright red urine. He remained free from glycosuria on a diet of 1,060 calories and two doses of 12 units of insulin a day. The urine became free from blood on the fourth day after this symptom had first appeared.

Perhaps the most interesting feature of this case is the complete absence of any acute infective process or septic lesion, as far as could be ascertained, which might have itself caused the haematuria. As Drs. Lawrence and Hollins have pointed out, all the cases so far recorded have been males—I am, etc.,

London July 2nd.

ARTHUR A. OSMAN

ROYAL COLLEGE OF SURGEONS MUSEUM ANNUAL EXHIBITION

Sir,—At the suggestion of Sir Arthur Keith, I beg to inform you, and those of the profession who are interested in the work of the Royal College of Surgeons of England, that there has been placed on view at the annual exhibition—which is open until July 28th—a series of new and original photomicrographs illustrative of the results of the process of osteolysis as it occurs in the oral cavity. Osteolysis is particularly well studied in this region and, although at present but little investigated already explains some of the pathological changes in the alveolar processes of the jaws and the dental articulation tissues which are universal in man and many of the lower vertebrates—I am, etc.,

Beckenham July 6th

ARTHUR HOPEWELL-SMITH.

ACUTE APLASTIC ANAEMIA

Dr. A. HAYES SMITH (Bradford), in a further letter on this subject, writes:

Your review in the *Journal* of June 25th (p. 1129) in answering the charges of inaccuracies preferred against him by Dr. Young and myself, states: "The actual figures for the two counts were 60 and 87 polymorphonuclears per cmm., it seems quite accurate to describe such a state of affairs as an absence of polymorphs." I have never previously encountered such an illogical and unjustifiable deduction in a scientific journal. A standard of such laxity that counts of 60 and 87 might be "quite accurately" described as *nil* needs no further comment. He commits an equally gross error when he refers to my use of the term "leukin," and states that it "surely means 'absence' of leucocytes." Reference in the glossary at the end of the book gives the accepted meaning of the term in haematology. Leukin is no more synonymous with "absence of leucocytes" than is "anaemia" synonymous with "absence of blood." The sweeping statement that "similar observations" (to those made by me) "are quite frequently to be made in secondary anaemia of various types" cannot be supported by reference to a single case in the literature, although Dr. Young and I have asked for such a reference.

Obituary

HENRY HANDFORD, M.D., F.R.C.P., D.P.H.,

Consulting Physician Nottingham General Hospital Consulting Medical Officer of Health for Nottinghamshire

We have to announce, with regret, the death of Dr. Henry Handford, one of the best known figures in the medical profession in Nottinghamshire, where he was medical officer of health for many years after having taken an active part in other spheres of medicine, notably in the work of the Nottingham General Hospital. He died at his residence at Southwell, Nottinghamshire, on June 24th, in his seventy-fourth year.

Henry Handford commenced his medical education at the University of Edinburgh, graduating M.B., B.S., with honours, in 1878, and obtaining the diploma M.R.C.S. Eng. in the same year. Subsequently he pursued his medical studies in Paris and Vienna, and in 1882 proceeded M.D. Ed. He obtained the Cambridge D.P.H. two years later, and in 1889 was admitted to the Fellowship of the Royal College of Physicians. The greater part of his professional life was spent in Nottinghamshire, where he soon gained a high place in the esteem of his fellows and was appointed physician to the Nottingham General Hospital, a position which he resigned in 1906 on account of the pressure of his duties in connexion with the public health services of the county. When he retired, early in 1926, from the post of medical officer of health for Nottinghamshire he had completed over twenty-six years' service in that capacity. During the war he held a commission as major in the Royal Army Medical Corps, being attached to the sanitary service.

The affairs of his profession absorbed much of Dr. Handford's leisure, and he gave his assistance freely to

various organizations. As a member of the British Medical Association he acted as honorary local secretary to the Annual Meeting at Nottingham in 1892, and was a member of the Central Council from 1899 to 1903. He had filled the office of president in the Midland Branch of the Society of Medical Officers of Health and in the Nottingham Medico-Chirurgical Society, and was a Fellow of the Royal Sanitary Institute, and a member of the Royal Medical Society of Edinburgh.

Dr F. H. Jacob writes: Those who knew Dr Handford well admired him equally for his excellence as a physician and for his qualities as an English gentleman. No man could be more kind and courteous than he at all times and under all circumstances. There was about him a refined dignity of bearing which compelled respect. A love of literature and music and a positive hatred of untruthfulness completed the picture of the true, cultured gentleman. As a physician he was learned, he was an extensive reader, but his knowledge was his own—acquired by diligent observation, and the most painstaking and exact examination of his patients, interpreted in the light of the most recent pathological knowledge, and his own most careful pathological investigations. As illustration of this one may recall a paper to the Nottingham Medical Society, in 1884, on bacteria, in which he showed pure cultures of pathogenic organisms. In 1885 he demonstrated microscopic preparations of *hilzarzia haematobia*, sections from cases of choreic insanity, and of myelitis, actinomycosis, and supposed malignant pustule. In 1904 he described a case of heart-block, showing the heart and sections of the gumma involving the bundle of His. Thus throughout the wide field of medicine did he keep abreast with the most recent scientific knowledge of his day. In his work as county medical officer of health he displayed the same character of thoroughness, extreme conscientiousness and courtesy to all with whom he worked that he had shown in clinical medicine. But clinical medicine suffered a grievous loss which remained a source of regret to his old friends for many years. On January 1st, 1916, his two sons were killed at the Hohenzollern Redoubt. From this terrible blow his kindly and sensitive disposition never properly recovered, and it tinged his later years with sadness.

EDGAR MARCH CROOKSHANK, M.B.,

Emeritus Professor of Bacteriology and Comparative Pathology,
King's College London

As recorded in our last issue, Professor E. M. Crookshank died suddenly on July 1st, at his residence at East Grinstead, in his seventieth year. He received his early education at King's College School, London, and later at King's College Hospital, obtaining the diploma M.R.C.S. in 1881, and graduating M.B. Lond., with honours in obstetrics, three years later. He had been one of Lord Lister's dressers at King's, and subsequently held the post of house-surgeon. In 1882 he was chosen for special duty on the staff of Sir James Hanbury, principal medical officer of the Egyptian expedition. Dr Crookshank was present at the battle of Tel-el-Kebir, and received the Egyptian medal and the Khedive's star; he prepared a report on the antiseptic methods employed in the hospitals in this expedition, and gave evidence before the Royal Commission on the Medical Services in Egypt. He then undertook bacteriological research in Paris and Berlin under Pasteur and Koch. He published in 1886 his well-known *Textbook of Bacteriology and Infective Diseases*, which passed through four editions. In the same year he was appointed professor of bacteriology at King's College, and was later put in charge of the first laboratory to be established in England for research and teaching in comparative pathology. On resigning his chair in 1889 he was elected a Fellow of King's College, and was appointed emeritus professor, and shortly afterwards published a work in two volumes entitled *The History and Pathology of Vaccination*. In 1894 he became a J.P. for Sussex, and from then onwards took an active part in public life, contesting unsuccessfully in 1906 the East Grinstead Parlia-

mentary Division as a Unionist and Tariff Reformer. He travelled widely in the Dominions, investigating the social and economic problems of the places he visited. For nearly forty years Professor Crookshank was one of the governors of the Royal Veterinary College, holding office as chairman of the General Purposes Committee, and of the Committee of Management of the Research Institute in Animal Pathology. At the time of his death he was deeply interested in a comprehensive scheme for the reconstruction of the existing college building in Camden Town.

FREDERICK THOMAS THISTLE, M.D.,

Senior Physician Torbay Hospital, Torquay

It is with deep regret that we have to record the death of Dr F. T. Thistle, which occurred on June 26th at Torquay. His passing removes a well-known and much esteemed figure from the ranks of the medical profession in South Devon.

Frederick Thomas Thistle was born at Whitby in 1859 and received his medical education at St. Bartholomew's Hospital, obtaining the diplomas M.R.C.S. in 1880 and L.R.C.P. in 1881. In the final examination for the former diploma he took first place in midwifery and was bracketed first in surgery. In 1889 he graduated M.D. Durham. After a term as resident medical officer at Stoke Newington and Clapham Dispensary he went to the Torbay Hospital as house-surgeon. Soon afterwards he commenced practice at Torre, and about the same time was appointed honorary visiting surgeon to the Torbay Hospital. He rapidly built up a reputation as a physician and obstetrician, and when the opportunity offered he transferred from the surgical to the medical side of the hospital, where for many years he presided ably over the meetings of the medical council. It was as an obstetrician of exceptional ability that he came to be best known, and his record of over 6,000 cases would be hard to equal.

A colleague writes: Dr Thistle was a man of the highest honour and integrity, energetic and untiring to the utmost degree. He avoided publicity and had no desire for civic or social honours. He was, however, a member of the British Medical Association and of the Torquay Medical Society, in the work of both of which he took the keenest interest, serving as vice-president of the latter body. Universally respected by his colleagues and deeply beloved by his patients, his kindly personality could ill be spared, and he will be greatly missed.

Dr WILLIAM TURNER, who died in tragic circumstances at his home at Hale, Altrincham, Cheshire, on June 25th, had been in practice in that district for over twenty years. He received his medical education at the University of Aberdeen, graduating M.B., Ch.B. in 1901, and continuing his studies later in Dublin and London. After serving in resident posts at the Crichton Royal Institution, Dumfries, and the Scarborough Hospital and Dispensary, he commenced practice at Hale, and soon built up an extensive connexion in that neighbourhood. During the war he held a commission as captain in the Royal Army Medical Corps, being awarded the Military Cross for his services. He was for a long period engaged on the Salonika front, and suffered considerably from ill health, the effects of which were apparent in his later years. In the affairs of his profession he played an active part: he was a member of the Manchester Medical Society and of the British Medical Association, and at the time of his death was a member of the Executive Committee of the Mid Cheshire Division of the Association. He was chairman of the Division in 1921, after holding various other offices. Dr Turner was a prominent figure in his profession in the Altrincham district, where he was recognized as an exceptionally able and conscientious practitioner. At the funeral service, held at St. Peter's Church, Hale, there were present many of his professional brethren, representatives of various public bodies, and members of all classes of society. Deep sympathy is felt for his widow and his young son.

Dr GEORGE SUTHERLAND, who died suddenly at Stornoway, in the Isle of Lewis, on June 28th, was among the best known members of the medical profession in the Outer Hebrides, where he had been in practice for the last seven or eight years. He received his medical education at the University of Edinburgh, and after graduating M.B., Ch.B. in 1910, served as house physician at the Royal Southern Hospital, Liverpool. Thereafter he spent several years abroad, in British Malaya and India and during the war held a temporary commission in the Royal Army Medical Corps. He was at one time medical officer to the station hospital at Quetta. At the end of the war he took up his residence at Invergordon in Ross-shire, but soon afterwards removed to Stornoway, where he was associated, as medical officer, with the work of the Lewis Hospital situated in that town. He was also medical officer for the parish of Stornoway. Dr Sutherland was an active member of the British Medical Association, and at the time of his death held office as vice-chairman of the Islands Division of the Northern Counties Branch.

We regret to record the death of Dr. Richard Dowden, principal medical officer, Federated Malay States, which occurred suddenly from heart failure at Kuala Lumpur, Selangor, on June 24th in his fifty-fourth year, on the eve of his retirement, after nearly twenty-five years in the Colonial Medical Service. He was the son of a well known professor of English at Trinity College, Dublin, where he himself received his medical education, graduating M.D., B.Ch. in 1898, and continuing his studies for a time at Vienna. In 1910 he obtained the Diploma in Tropical Medicine of the University of Liverpool. The greater part of his professional life was spent in the medical service of the colonies. In his earlier years Dr Dowden was employed in the West Indies, where he was a assistant medical officer in the Government Lunatic Asylum at Kingston, Jamaica. Subsequently he was transferred to the Federated Malay States, in which he was appointed principal medical officer in 1922, after being, for a period, senior officer in Penak. He had served as a lieutenant in the Royal Army Medical Corps. A colleague writes: "An impulsive and kind-hearted Irishman, Dr Dowden will be much regretted by his friends, who had hoped that he would spend many happy years of well-earned leisure at home."

The following well-known foreign medical men have recently died: Dr HENRIQUEZ, professor at the Collège de France and member of the Institut and Académie de Médecine; Dr ISRAEL DE JONG, an eminent Paris physician and authority on tuberculosis and respiratory diseases; Dr HANS SCHELBE, senior physician to the Children's Hospital and professor of pediatrics at Bremen, aged 50; Professor HJALMAR SCHIÖTZ, an eminent Danish ophthalmologist, aged 77; Dr J. H. CHARTIER, emeritus professor at the Naval University at Montreal and formerly president of the College of Physicians and Surgeons of the Province of Quebec; Dr XAVIER ARNOZAN, honorary professor of clinical medicine at Bordeaux and editor of the *Journal de Médecine de Bordeaux et de Sud-Ouest*, aged 76; Professor H. MARCHAND, a prominent pathologist of Leipzig, aged 82; Dr LUDWIG LICHTHEIM, professor of internal medicine at Königsberg; Dr JULES MOUTET, professor of oto-rhino-laryngology at Montpellier, aged 62; Dr ANSEL FERNÁNDEZ CARO y NOUVILLAS, president of the Spanish Society of Hygiene and vice-president of the Royal Spanish Academy of Medicine; Dr NEWTON MELMAN SHAFFER, emeritus professor of orthopaedic surgery, Cornell University Medical College, and past-president of the American Orthopaedic Association, aged 81; Professor KARL GARNÉ, who recently retired from the chair of surgery at Bonn University; Professor HROO KARL PLAUT, the Hamburg pathologist, aged 69, whose name is often used in Germany in association with that of Professor Vincent of Paris as a synonym for ulceromembranous angina; Dr NARCISSENTO GUNOEL, professor of children's diseases at Rio de Janeiro and Professor MEYER-WITZ, a Zürich gynaecologist, aged 66.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons this week discussed Estimates for the Home Office and Post Office, completed the Committee stage of the Valuation (Ascertainment) Bill, and made progress with a number of other bills. A meeting of the Parliamentary Medical Committee had been arranged, but has been postponed till next week.

Scottish Board of Health

In the House of Commons, on July 9th the Reorganization of Offices (Scotland) Bill was considered on the Report stage. The measure provides that the powers and duties of the Scottish Board of Health, the Board of Agriculture for Scotland, and the Prison Commissioners for Scotland shall cease to exist from the appointed day and shall be transferred to a Department of Health for Scotland, a Department of Agriculture for Scotland and a Prisons Department for Scotland respectively. Mr. HANLEY moved to delete the provision abolishing the Scottish Board of Health.

Sir J. CHALMERS, resisting the amendment, said that the new system would lead to greater efficiency. Under that system there was nothing to prevent the technical officers from coming into the closest possible touch with himself or with the Under-Secretary for Health. In his judgement a responsible head of each department, with the full responsibility of his office, and with the knowledge that he had to give advice to his Minister, was infinitely preferable to the system of boards. From experience he had found that in a case of urgency it was much preferable to have a head of a department to whom he could go than to have to submit a question to the chairman of a board who would have to consult the members, who might have conflicting opinions on a question. With regard to the technical experts, he was prepared to give them every opportunity to express their views, in close consultation with the head of the department and with the Minister, but the final word must be with the Minister and with Parliament and not with the experts. If the medical man of science, for example, had his way, he might very possibly impose upon the House of Commons and the country a system eminently desirable in itself but so extravagant, or so much in advance of the times that Parliament could not tolerate it. Hon. members had said that it was desirable that some undertaking should be given that those in the present boards would be fairly treated in the changes that were to be made. That, undoubtedly, would be done. Unfortunately the chairmen of the Board of Health, a doctor who was well known to members of the House, had had to retire through ill health. There had never been a time in the history of the administration of the offices in Scotland when this change over would be made more easily and with less disturbance and difficulty so far as the individuals were concerned.

Dr. SHIELDS said that the Secretary for Scotland had not shown that to change from the board system to that of the departmental system was necessarily moving with the times. The board system suited the genius of the Scottish people. In all departments of industry the technical expert had become much more important. This bill showed no method by which the Minister could be kept in touch with the technical experts. Under the new system in the Scottish Board of Health the heads of the Medical Department, the National Health Insurance Department, the Pensions Department, and the Law Department would have to go back one step. Their decisions and advice would then go to the Minister by way of this new chief of the department, who would be a civil servant with no technical knowledge and who would not be in a position to give any greater weight to the views of his experts than the right hon. gentleman himself. The right hon. gentleman by this system was letting somebody else make up his mind for him, with no better authority and ability to do it, and probably with less. Instead of having direct access to the Minister the technical men would have less. They would have to go through this civil servant and their views might or might not be done justice to. The Minister had said that there was no reason why the experts should not come to see him. If that was the case what would become of the discipline in the department if, behind the back of the chief of the department, any of the technical heads were to go to the Minister and give, perhaps, different advice from that tendered by the chief himself? The future position of the Board of Health was one of the greatest tragedies which this bill would bring about. The Board of Health was a most efficient and up-to-date department. It had done a great deal of work, not only in administration but in stimulating and strengthening Scottish local authorities in various directions. That work could only be less and not more efficiently performed as the result of the changes in

this bill. He (Dr. Shuels) wished to know why there was such delay in filling the vacant medical posts under the board. Were they going to see an example of the anglicizing process in Scotland by individuals being appointed from the Ministry of Health to fill the vacancies?

The amendment was rejected, the Report stage was concluded, and the bill read the third time.

Coroner's Law and the Pace Case

In the House of Commons, on July 8th, Mr. PURCELL asked the Prime Minister whether he would consider the case of Mrs. Pace, the widow who had been subject to a protracted coroner's inquiry had been arrested on a charge of murder and had now been released, no case having been proved against her. Mr. Purcell further asked whether the Prime Minister would institute a public inquiry into the position and powers of coroners.

Sir T. LASKER replied that the proposal to hold a public inquiry into the legal position of coroners would receive due consideration by the proper authorities.

Mr. MORRIS asked if Sir T. Lasker proposed to introduce an amendment of the law relating to coroners' juries and limiting the power of such juries to inquire into the cause of death only, leaving the verdict to be inquired into by the magisterial courts and the assize court.

Sir T. LASKER: I did not say that the Government are contemplating an inquiry into the question of coroners' inquiries. What I said was that the question will receive due consideration from the proper authorities.

Bills

In the House of Lords, on July 9th, the Child Destruction Bill (formerly the Infanticide Bill) was recommended to a Committee of the whole House. Lord DALRYMPLE formally moved that the amendments which had been made by the Select Committee to which the bill had been sent, should be agreed to. This was done and the bill passed through Committee.

On July 9th the Dogs Bill was considered and passed through Committee in the House of Lords.

In the House of Lords, on July 10th, the Marriage (Prohibited Degrees of Relationship) Bill and the Reorganization of Offices (Scotland) Bill were read the first time.

Motor Traffic Danger

On July 10th in the House of Lords, Lord LAMINGTON asked what effect one way thoroughfares had had on the number of accidents to pedestrians in the metropolitan area, the number of accidents to pedestrians for the twelve months preceding the date of the last return, and if the Government had any proposals for making the thoroughfares less dangerous to people on foot. Lord DE CURTAIN said that a large percentage of people killed and injured by motor traffic were children and policemen should be posted outside all schools on main roads to assist the children in crossing. Strict tests should be imposed on every person who applied for a driver's licence. Lord MORRISON or BEAULIEU said that the report of the Commissioner of Police for 1927 showed that of 1,027 fatalities 528 were attributed to pedestrians crossing the road without due care and 116 to hesitation and faltering. There was such a thing as walking to the public danger as well as driving. Taken as a whole, the one-way system had been a success. Before long escalators would have to be provided either under or over the streets to enable pedestrians to cross with some convenience. The results of a very large number of coroners' inquests all over the country showed that 36 per cent only of the accidents were avoidable by drivers and 64 per cent were unavoidable. Earl RUSSELL said that the mortality among children was a very regrettable feature. A great deal had been done by giving instruction in the schools on this matter but it took time, probably a generation to get people used to the fact that the roads were now in reality unfenced railway tracks. The old bogey of a test for drivers had been considered by various committees for years and years and they had all come to the conclusion that skill in driving was not the same as care in driving. Viscount CURZ said it was a serious matter that in the whole country last year 4,000 people were killed and 160,000 injured by motor traffic. The great majority of these cases would not have arisen if the vehicles had not been driven so fast and if proper care had been taken by drivers. He asked the Government to appoint a departmental committee to go into the question of increasing the safety of the roads. Viscount PERT said that the question of street accidents was engaging the attention of the Home Office and the Ministry of Transport and was a very difficult problem to deal with. It was not the experience of the Ministry of Transport that many of the accidents had been due to the roundabout and one-way system of traffic. These systems had not been in force long enough to be judged in that respect. It was hoped that as the public became more familiar with them the number of accidents would be considerably reduced. In the effort to make the streets less dangerous, refugees had been provided and crossing signs which police had been stationed at the crossings. Special investigations were being made as to the streets where the greatest number of accidents took place. The London Traffic Advisory Committee was going into the question of accidents to children and hoped to be able to report on the whole problem very soon.

Voluntary Hospitals and Motor Accident Cases

Colonel ASKLES, replying to Mr. Horre Belshah and Sir J. Marriott on July 10th, said that he had received a copy of a resolution calling attention to the heavy and increasing burden imposed on voluntary

hospitals in the treatment and maintenance of motor accident cases. The compulsory insurance of all motor vehicles would involve great difficulties but even if they could be overcome he did not think that it would be practicable to make the cost of treatment and maintenance in voluntary hospitals a first charge on the insurance moneys. In order to bring the matter within the scope of a policy of insurance it would be necessary, in the first place, that the hospital should have an enforceable claim against the patient and in the second that the patient's injury, if he was a third party, should have been due to negligence on the part of the driver of the vehicle.

National Insurance Change of Doctor—Sir KINGSLEY WOOD told Sir H. Brittain on July 4th, that representations from the London Insurance Committee relating to the conditions under which an insured person who proposed to transfer himself from the list of one insurance practitioner to that of another could obtain immediate treatment from the second practitioner were received by the Minister of Health on July 3rd. He was not yet in a position to reply to the hon. member on the matter.

Industrial Poisoning—On July 4th Sir W. JOYNSON HICKS told Mr. W. Thorne that his attention had been called to the report of the Battersea coroner on the inquest on two girls who died in hospital following illness which they contracted while employed at a scouring powder works at Battersea. A full report had been submitted to him by the medical inspectors of factories who attended the inquest and investigated the circumstances. In the opinion of the medical inspectors these cases originated when the mixing and filling of the powder were done by hand. At the beginning of 1927, on the instructions of the district inspector of factories mechanical methods of working were introduced. The plant since that date had been totally enclosed and exhaust ventilation applied to all points where dust was liable to escape. He was advised that the present arrangements should prove effective, but they would continue to receive close attention.

Lead Poisoning—Sir W. JOYNSON HICKS, replying on July 5th to Lord H. Bentinck, said that 33 cases of lead poisoning among painters were reported in the first five months of 1927 and 40 in the same period in 1928. All cases of lead poisoning and complaints were fully investigated by the factory inspectors. It had always been recognized that on account of the special conditions under which the industry was carried on it would be necessary to rely to a large extent on the co-operation of the industry itself for securing general compliance with the regulations. With this object conferences were arranged with the employers and operatives' associations. Both sides had taken steps to impress on their members the importance of a strict observance of the regulations and had promised to assist the department in every possible way.

Vaccination—Mr. CHAMBERLAIN, replying to Sir B. Peto on July 5th, said that he had received representations from boards of guardians as to the risk to the community from unvaccinated persons. The question of making any change in the present facilities for the exemption from vaccination of infants in view of the spread of small pox would be considered in connexion with the report of the committee on vaccination about to be published.

Medical Examination of Vagrants—Mr. CHAMBERLAIN on July 5th told Captain Fairfax that he had received an appeal from the Norfolk Vagrancy Committee for assistance in providing extra remuneration for medical officers of Poor Law institutions now called upon by order of the Ministry of Health to examine all casuals for small pox. He could not however undertake to defray all or part of the additional fees involved in view of the fact that this work was outside the duties ordinarily performed by those doctors. There were no funds at his disposal out of which such a contribution as was suggested could be paid. Captain FAIRFAX asked if the Minister expected these doctors to do the extra work gratis or did he expect the local authorities to defray the extra cost. Mr. CHAMBERLAIN said that he had no power to make any contribution. Mr. SHEPHERD asked if the right hon. gentleman would see that the medical officers undertook the inspection of casuals in the evening and thus give some value to their inspection. Mr. CHAMBERLAIN replied that that would certainly involve a claim for an extra fee. Sir KINGSLEY WOOD informed Lieut. Colonel Troyle, on July 10th, that thirty-six boards of guardians had forwarded resolutions in favour of making the cost of inspection of casuals for small pox a national charge. In reply to the question whether he proposed to take any action in the matter he referred the hon. member to the reply given on July 5th.

Mental Deficiency—The DUCHESS OF ATROLL, replying on July 9th to Mr. Harris, said that the President of the Board of Education hoped that the report of the special committee set up in 1923 to investigate various problems relating to mental deficiency would be available before the end of the year and that it would be published.

Grants for Health Purposes—Mr. CHAMBERLAIN in a tabular answer to Sir N. Grattan Doyle on July 5th stated that the percentage grants to local authorities in England and Wales, for the latest year available for tuberculosis was £1,640,098, for maternity and child welfare £767,082, welfare of the blind £5,195, venereal disease £302,158 and mental deficiency £505,642—a total of £3,218,175. In addition percentage grants amounting to £317,775 were made to voluntary associations as follows: maternity and child welfare £197,119, welfare of the blind £112,062, venereal disease £152 and mental deficiency £28,422.

Maternal Mortality—Mr CHAMBERLAIN on July 5th told Mr Groves that in 1924 the deaths due to childbirth in England and Wales were 2,847 with a percentage of 3.90 per 1,000 live births. In 1925 the figures were 2,900 deaths percentage 4.03 1926 2,860 and 4.12, and 1927 (provisional figures) 2,690 and 4.11. In 1924 in West Ham there were 12 deaths with a percentage of 1.66 in 1925 20 deaths percentage 2.85 1926, 13 and 1.91 and 1927 (provisional figures) 18 and 3.00.

Defective Children—On July 5th the DUCHESS OF ATROLL in reply to Mr Harris said that according to the information in the possession of her department 240 local education authorities had provided no special schools of their own for mentally defective children and 257 had provided no special schools of their own for physically defective children but 131 of the former authorities and 221 of the latter sent children of these types to special schools provided by other authorities or by voluntary managers. Some 200 authorities made provision for the orthopaedic treatment of crippled children. In addition about 50 authorities had arranged for the supervision of mentally defective children in their areas. The Board of Education already had before it proposals for the provision of five new schools for mentally defective children and twenty-eight new schools for physically defective children.

Notifiable Diseases—Mr CHAMBERLAIN in reply to Mr Groves on July 5th said that his department received from the local medical officers of health each week particulars of the numbers of cases of notifiable diseases occurring in their areas and the crude attack rates for each year per 1,000 of the civilian population were worked out from the figures so supplied. Measles was not a notifiable disease in any of the administrative areas included in the West Ham Union but particulars of the numbers of cases and the attack rates of diphtheria and scarlet fever in each of these areas had been published for 1924 1925 and 1926 in the Registrar General's statistical review. Similar particulars for 1927 and 1928 would be published in due course in the statistical review for these years.

London Lock Hospital—On July 9th Sir KINGSLEY WOOD informed Mr Potluck Lawrie that he understood that the committee appointed by him last March to inquire into the management, administration and staffing of the London Lock Hospital, with special reference to the arrangements for the medical treatment of patients had held six meetings and had in addition visited a number of institutions. He was informed that the inquiry was approaching completion but that the committee was not yet able to say when it would conclude its labours.

Anthrax in Man—Sir W. JOYNSON HICKS in reply to Dr Salter on July 5th stated that the number of cases of anthrax in human beings which had been notified to his department in the years from 1923 to 1927 were 50 45 48 42 and 35 respectively of which 8 4 10 4 and 3 were fatal. In all except seven of the cases the patient was found to have been in contact with materials likely to be infected with anthrax. Sir W. JOYNSON HICKS also told Dr Salter that each of the cases of anthrax at Newcastle Warrington and Bolton reported this year had been investigated. It was found that in every case except one the workman had been in contact with hides imported from China. The question of further precautions had for some time past been under discussion with the employers and workers' associations but it was agreed that the only measure likely to be effective would be disinfection. Investigations for this purpose were commenced some time ago by the United Tanners' Federation and were being actively pursued but no satisfactory method had yet been worked out. The issue of a draft welfare order was now under consideration and he hoped that a decision would be reached very shortly.

Haydock's Infantile Mortality—Mr CHAMBERLAIN in reply to Mr R. Young on July 10th said that the attention of the Minister of Health had been called to the annual report of the medical officer of health for Haydock Lancashire which showed that while the death rate was slightly below the average for England and Wales the infantile death rate was 14 per 1,000 higher. He proposed to arrange for a local investigation of all the circumstances.

Prescriptions for Food Products—Mr CHAMBERLAIN on July 5th answering Miss Wilkinson who asked whether certain insurance committees had decided that insurance practitioners must not order for their patients vitamin preparations on the ground that they were not drugs but food while other committees allowed doctors to prescribe vitamin preparations and that the question whether any particular preparation could be regarded as a medicine within the meaning of the National Health Insurance Acts was one to be determined by the local Insurance Committee and would only come before him formally on an appeal from their decision. He was aware that there was a divergence of practice between committees on the point, and he proposed to issue a statement to assist insurance practitioners and committees in their consideration of it in future.

Overcrowded Dwellings—On July 4th Sir KINGSLEY WOOD informed Admiral Beamish that as the large numbers of houses which had been built in recent years had exceeded the requirements of the increased population it was obvious that they must largely towards the relief of overcrowding in the slums. He had no later information persons per room than the statistics contained in the census. Those figures were not confined to

Rating of Hospitals—Sir KINGSLEY WOOD on July 4th told Sir C. Rawson that the Minister of Health had received communications from the British Hospitals Association and from the authorities of certain hospitals as to the effect of the operation of the Rating and Valuation Act of 1925 on hospitals and similar institutions. He had received no such communication from local authorities. Sir C. Rawson asked if Sir Kingsley Wood was aware that the Sussex County Council had had its assessment raised from £100 to £1,600 and if the assessment committees of the different localities were justified in making nominal assessments, as they had done hitherto. He asked if the House would have any opportunity of discussing the matter at an early date, as it affected so many hospitals all over the country. Sir KINGSLEY WOOD replied that if assessment committees were not acting properly and within the law there was a remedy by way of appeal.

Income Tax Children's Allowances—During the discussion of the Finance Bill in the Committee of House of Commons on July 3rd Mr GATES moved a new clause to extend the allowance granted to parents of children receiving full-time instruction at a university college school or other educational establishment to parents obliged by their financial circumstances to apprentice their children to trades or to article them to professional people. He said that a great many professional people such as the widows of lawyers doctors and so on had to maintain their children at home while they were apprenticing them to business or articling them to lawyers or accountants. It was very unfair that the better class of parents who could afford to send their children to the university, should have the benefit of the allowance while parents of the poorer classes of professional people could not get it. Dr FLIORE resisted the new clause which would permit an allowance to be made indefinitely while the children of the claimant were learning a trade or profession. Mr GATES said who was a professional man would realize that even professional men were kept by their parents up to rather an advanced age. It was not supposed that a surgeon could make much more than his laundry bills until the age of 40 and it would be quite unreasonable to expect the Inland Revenue to keep track of such people up to such an age. The clause was negatived.

The Services

DEATHS IN THE SERVICES

Deputy Inspector General William Digby Longfield, R.N. (ret.) died at Plymouth on May 23rd aged 89. He took the T.R.C.S.I. in 1860 and entered the navy as assistant surgeon on October 4th 1861. He served in the Abyssinian war of 1868 in that rank, in the frigate *Octavia* and in the sloop *Spartan*. On May 1st 1875, he was promoted to surgeon and when serving in H.M.S. *Tenedos* landed in charge of the contingent from that vessel to the naval brigade in the Zulu war of 1879. He then served as senior medical officer first on the Lower Tugela and afterwards with the Ekowe relief column was dangerously wounded by a gunshot wound of the chest in the battle of Gungahlovo on April 2nd 1879 was twice mentioned in dispatches and received the Zulu medal with a clasp, also the thanks of the Commander in Chief, Lord Chelmsford and special promotion to fleet surgeon with seniority from July 31st 1879. In the same year he received the Gilbert Blane gold medal for the best medical journal of the year. In 1891 he was appointed fleet surgeon at Devonport Naval Barracks and retired on October 16th 1893 with an honorary step as D.I.G. On March 20th 1904, he was granted a Greenwich Hospital good service pension.

Colonel George Hutcheson, Bengal Medical Service (retired), died on May 21st, aged 83. He was born on June 27th 1844 the son of Mr John Hutcheson of Glasgow, took the Edinburgh double qualification in 1868, and graduated as M.B. and C.M. Glasgow in 1869, and as M.D. in 1871. Entering the Indian Medical Service as assistant surgeon on October 1st 1868, he attained the rank of surgeon colonel on October 1st 1897, and retired on October 1st, 1902. After a few years of military duty he was posted to civil employ in the North-West Provinces now the United Provinces of Agra and Oudh. There he served chiefly in the sanitary department becoming sanitary commissioner of the province in May, 1869. He was posted to the Central Provinces in May 1896, as acting inspector general of civil hospitals, confirmed in that post a year later and in May 1899 transferred in the same capacity to the United Provinces. He was the author of a work *Cholera its Causes and Mode of Dissemination*, 1885. His son entered the I.M.S. shortly before his retirement, and is now inspector general of civil hospitals in Assam.

Lieut Colonel James Stuart Brooke V.D., late of the East Indian Railway Medical Service died at Charlton Kings, Cheltenham on May 17th aged 71. He was educated at Trinity College Dublin and took the L.R.C.S.I. in 1880 and the L.K.Q.C.P. in 1881 also the F.R.C.S.I. in 1896. After qualifying he took an appointment in the medical service of the East Indian Railway, in which he served for about thirty

Mr Ganjee becomes substitute Member of Council for the late Mr Thelwall Thomas until July, 1935

Medical News.

THE secretary of the British Empire Cancer Campaign informs us that the number of those who have signified their intention of being present at the International Cancer Conference in London next week is already very large, and having regard to the limited space at the Royal Society of Medicine and the College of Nursing, where the scientific meetings are to be held, it will be necessary to confine admission (which will be by ticket only) to official delegates and to a small number of others who specially desire to be present. Those wishing to attend should apply to the secretary, International Cancer Conference, Royal Society of Medicine, 1, Wimpole Street, W 1.

THE annual meeting of the British Institute of Philo-sophical Studies will be held at the Royal Society of Arts, 18 John Street, Adelphi, W C on Monday July 16th, at 5.30 p.m., when the Earl of Balfour will preside and deliver a short address.

THE tenth annual meeting of the Mental Hospitals Association will be held at the Guildhall, London, on July 18th, at 11 a.m.

A MEETING of medical Freemasons interested in the formation of a British Medical Association lodge will be held in Manchester at 8, S. Peter's Square, on Wednesday next July 18th, at 4 p.m. The meeting has been arranged for the benefit of those who may not be able to attend the function at Cardiff owing to the distance. All medical Freemasons are invited. It is expected that Bro. Bristowe and Bro. Howell Evans, two provincial grand officers and leaders in the present venture, will address the meeting.

FOUNDER'S DAY will be celebrated at Epsom College on July 28th, when Lord Riddell will present the prizes. At midday there will be a service in the chapel, and in the evening a choral performance of *Isidore* by the College Musical Society.

THE Fellowship of Medicine and Post Graduate Medical Association announces that a special course in diseases of the chest will be given at the Brompton Hospital in the week beginning on Monday July 30th. A four weeks course in urology begins on August 7th at the All Saints Hospital, and a fortnight's course in diseases of infants begins on August 13th at the Infants Hospital. From August 27th to September 8th a "refresher" course in medicine, surgery, and the specialties will take place at Queen Mary's Hospital, Stratford, occupying the whole of each day with the entire hospital open to post-graduates during the course. Copies of all syllabuses and information regarding the Fellowship's general course may be obtained on application to the secretary to the Fellowship, 1, Wimpole Street, W 1.

ACTING on behalf of his father, the Duke of Connaught, who was absent through indisposition, Prince Arthur of Connaught, on July 10th, laid the foundation stone of the New Bethlem Hospital, which will stand on a site occupying 330 acres of the Monks Orchard Estate at Shirley, Surrey, and will permit extensive developments not possible at the existing institution in Lambeth Road. Sir Charles Wakefield, president of the hospital, mentioned that the Bethlem Royal Hospital was founded for the treatment of mental disease many centuries ago. It is intended to erect detached buildings for patients and a separate science and treatment unit containing the pathological, bacteriological, psychological, dental, electrical, x-ray, and operating departments. A gift of £25,000 from the president will provide the "Sir Charles Wakefield Science and Treatment Departments" and the "Lady Wakefield Chapel". Lady Cooper has given £5,000 for the main recreation hall in memory of the late Sir E. E. Cooper. An appeal for £120,000 is being made to permit the opening of the new hospital free of debt, and it is pointed out that this is the only appeal made for the hospital within living memory.

THE annual report of the British Science Guild was presented to the general meeting of the guild on June 21st. The report deals with the activities of three committees, one is engaged in inquiring into "the position of the teaching of introductory science and nature study in elementary schools and central schools," a second is studying problems of reform in the patent laws while the third is concerned with the alleged failure, both in Government departments and in industry, to make adequate use of the knowledge and abilities of technical experts. It is stated that elementary science occupies a worse position to day in most primary schools than it did twenty years ago. Industry is said to be hampered by the insecurity of British patent laws, and by the existence of large numbers of "paper" patents while inventors are burdened with charges some of which are absorbed, as with the taxes on motorists into revenue for general expenditure. With regard to technical experts the British Science Guild

considers that a "root and branch" reorganization of Government departments is necessary in order that proper status may be given to professional officers in the public services. As an addendum to the report short accounts are given of some recent developments in the application of science to national life. They include an account of the production of vitamin D on a large scale by irradiation of ergosterol.

NEW public baths, erected at a cost of £37,000, were formally opened at Lytham St. Anne's, Lancashire, by Sir William Milligan on June 9th. In addition to a large swimming bath the scheme comprises an extensive suite of remedial baths, designed to permit the development of the Lancashire borough as a seaside spa. Various types of douches, shower and needle baths, mustard, sulphur, and pine baths, vapour baths, etc., in fresh water and sea water have been provided, and there are also facilities for radiant heat and artificial sunlight treatment. Sir William Milligan, at the opening ceremony, emphasized the value of the baths and the auxiliary establishments as a treatment centre, notably for rheumatism, and suggested that they had in the new institution an opportunity for a great anti-rheumatic ellipse. He pointed out that the outcome of the corporation's venture would depend alike on the support of the public and the co-operation of the medical profession.

THE second summer meeting of the British Pathologists Association, held in the pathological department of the Royal Infirmary, Chester, on June 30th, with Dr. W. H. Grace in the chair, was devoted to the discussion of the methods used in the examination of the blood. Dr. J. C. Greenfield demonstrated the malug and staining of blood films, the differential count of the white cells, enumeration of the red and white cells, the estimation of haemoglobin by the Hellige method, and the reticulocyte count. Dr. A. Reashaw described the examination of the blood for parasites and the presence of organisms, and Dr. S. C. Dyke dealt with the platelet count, the grouping and matching of bloods, and the determination in the blood of cholesterol, bilirubin, and faecal phephates. Dr. W. H. Grace discussed the estimation of the blood sugar by the Folin Wu method and Dr. A. G. Shorlits estimation by MacLean's method and the determination of the blood urea by Kennaway's method. Dr. A. T. Sladden described the estimation of the blood urea by a modification of MacLean's method and Dr. W. E. Carnegie Dickson the estimation of the serum calcium. The staff of the Chester Royal Infirmary entertained the members of the association at dinner in the evening.

MR. W. P. SYMES, of Messrs. H. K. Lewis and Co. Ltd., delivered a lecture, on July 6th, at Gordon Hall School of Pharmacy for Women, Gordon Square, W.C., on medical book-keeping and the duties of a dispenser book-keeper in general practice. The lecture was illustrated by demonstrations and was followed by questions and discussion and the principals of the school decided to add this subject to their syllabus.

ON his retirement from office as surgeon to the "S" Division of the Metropolitan Police, Dr. James Manghan was on July 4th, at Albany Street Police Station, presented with a portfolio from the officers and men of the division. In returning thanks Dr. Manghan recalled that his connexion with the division began in 1886, and referred to the various aspects of his work, remarking upon the satisfactory nature of his dealings with the superior officials of the force, and stating that the relations between the inspectors, sergeants, constables, and himself had always been most cordial. He concluded by saying that he was proud of his long association with the Metropolitan Police, and of the fact that the best years of his life had been spent in its service.

DR. ARTHUR WESTERMAN has been elected president of the Hentorian Society for the coming year, and Mr. W. E. Tanner and Dr. D. C. Norris honorary secretaries.

A CIVIL list pension of £100 has been granted to Mrs. Strangeways in recognition of the services rendered by her husband, the late Dr. T. S. P. Strangeways, to the cause of medical science.

THE Mental Hospitals Committee of the London County Council has had under consideration the question of revising the salaries of the three technical assistants to the director of the pathological laboratory at Maudsley Hospital. The committee has come to the conclusion that the basic salaries, which were fixed in 1919 and 1925 are not adequate. It is proposed that for the chief assistant to the pathologist (a professional man with scientific qualifications) the basic rate shall be £400 a year (instead of £350) rising by annual increments of £25 to £600 a year. With regard to the second and third assistants, these have had a minimum respectively of £250 and £120, rising by annual increments of £20 and £10, to a maximum of £350 and £150. It is now proposed to increase the maximum basic salaries of the

present holders to £400 and £250 respectively. The salaries mentioned are subject to temporary additions on the basis approved by the Council in 1920, so that the total remuneration at £600 will be £776, at £400, £547, and at £250, £361.

THE third ordinary general meeting of the Ross Institute and Hospital for Tropical Diseases was held on June 28th. The chairman, Sir Charles McLeod, in dealing with the annual report, commented on the cancer investigation of Dr. Shaw Macleuzie, which had been continued by an independent investigator from the electro-physical standpoint. The chairman called attention to the appeal for an endowment fund of £250,000, and also to the need of obtaining £30,000 for extending the laboratories and hospital wards. He emphasized the importance of creating a central industrial antihumoral advisory board, and mentioned that it would be presided over by Sir Malcolm Watson, who intended to visit some part of the tropics each year for a short period.

A MEDICAL practitioner, Dr. C. H. Vernon, of Boscombe, Bournemouth, won the *Daily Telegraph* Cup at Bisley on July 9th, being the only competitor to secure a "possible" among about a thousand who entered. Dr. Vernon last year won the King's prize. He served during the war, first as a combatant officer with the Hampshire Regiment, later holding commissions successively in the R.A.F. Medical Service and in the R.A.M.C., having graduated M.B., B.Ch. Camb. in 1918.

THE proceedings of the Conference on Rheumatic Diseases, held at Bath on May 10th and 11th have now been published in book form by the Hot Mineral Baths Committee of the Bath City Council at the price of 5s. (5s. 3d. by post).

IN conjunction with the Second International Congress of Radiology, to be held at the end of this month at Stockholm, will be an exhibition of apparatus in the Parliament House, including an exhibit of British-made x-ray apparatus contributed by the leading firms in this industry. This is the first occasion on which it has been possible for British manufacturers to show their products on a large scale at such a congress outside Great Britain.

LONDON was to intend to visit the first International Congress of Oto-Laryngology, at Copenhagen, from July 30th to August 1st, are asked to forward their subscriptions without delay. If this has not already been done. As previously announced the membership subscription is 30 Danish kroner and 15 Danish kroner for each lady accompanying a member. Payment may be made by an English cheque, which should be forwarded to the honorary treasurer, Dr. Jørgen Vøller, Vestre Boulevard 13, Copenhagen. On receipt of this a programme of the festivities and excursions will be dispatched from Denmark, together with a form of application for tickets. Hotel accommodation may be obtained through Bennett's Tourist Office, 45 Raadhuspladsen, Copenhagen V, and particulars and tickets for the journey from Messrs. Bennett, 66, Haymarket, S.W. 1, or Messrs. Thomas Cook and Son, Berkeley Street, W. 1.

THE issue of *Upsala Lakareforenings Förhandlingar* (Proceedings of the Upsala Medical Association) for June 16th is dedicated to Dr. Ulfrik Quensel, professor of pathology at Upsala, on the occasion of his 65th birthday. It contains nineteen papers, fourteen of which are in German, three in Swedish, and two in English (Plagino in Sweden in 1927, by G. Naeslund and R. Strömar, and the genesis of tumours, by W. Bosmans).

A POST-GRADUATE course on balneology and balneotherapy will be held at Carlsbad from September 23rd to 29th, when lectures and practical demonstrations will be given. Professor Hugh MacLean will speak on the treatment of gastric and duodenal ulceration with large doses of alkalies, and Dr. George Graham will deal with the cause of the diminution of sugar tolerance in diabetes. Special travel and excursion facilities are available to medical practitioners and their friends attending the course. Further information may be obtained from Dr. Edgar Ganz, Carlsbad, Czechoslovakia.

A CONFERENCE of German societies concerned with the treatment of juvenile neuropathies will be held at Hamburg from September 13th to the 15th. Dr. Villiger of Hamburg will read a paper on the education of the public in this connection. Dr. Frankwood Williams of New York will describe the efforts made in America to prevent juvenile delinquency, and there will be short contributions on various aspects of education and preventive treatment together with visits to local institutions. Further information may be obtained from Professor F. Siegmund-Schultze, Potsdamer Strasse 118 C, Berlin W. 35.

THE tenth Congress of the Association of French speaking Physicians of North America will be held at Quebec, under the presidency of Dr. Duguean, from September 5th to 7th, on the occasion of the twenty-fifth anniversary of the foundation of the association. The two principal subjects for discussion will be puerperal infection and diphtheria.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to *The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C. 1*.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C. 1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are JULY 1928 9561 9562 9563 and 9564 (internal exchange four lines).

THE TELEGRAPHIC ADDRESSES are EDITOR of the *British Medical Journal*, *Antology, Westcent London*.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westcent London*. MEDICAL SECRETARY, *Mediscern, Westcent London*.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Facilis Dublin* telephone 62550 Dublin) and of the Scottish Office 7 Drumheugh Gardens, Edinburgh (telegrams *Asoci Edinburgh* telephone 24361 Edinburgh).

QUERIES AND ANSWERS

COINS

H. A. wishes to learn of any suggestions for the relief of cure of corns on toes and soles of feet. He has found the usual remedies quite useless in most cases, as also the advice to wear sensible shoes.

VAGINITIS AND PROCTITIS IN CHILDHOOD

M. S. asks for suggestions for the treatment of vaginitis and proctitis in a healthy child of 2 years and 3 months. Investigation has shown gonococci and intestinal worms absent.

INJECTION TREATMENT OF VARICOSE VEINS

DR. GERARD STOT (London) writes in answer to G. W. I. S.' query (*British Medical Journal* July 7th p. 39) to say that the injection treatment of varicose veins is practised at the Royal Waterloo Hospital on Tuesday afternoons.

INCOME TAX

Benefit of Free Board and Lodging

SOME weeks ago a correspondent explained that he was engaged as a temporary assistant on terms which gave him free board and lodging at the expense of his principal though not under the latter's roof. The local income tax authorities had claimed to include the value of that advantage in his assessment to tax, but, acting on our advice, he contested the validity of that view and has now informed us that the issue has been settled by agreement to his complete satisfaction. With the best will in the world taxing authorities scattered about the country must no doubt be occasionally guilty of error, but there is one feature of this case which induces the opinion that it may be typical of others where the official error persists, and that is that unlike other errors against the taxpayer's interest it is not inherently unreasonable. From the assistant's point of view he may well regard the provision of free board and lodging to the value of £4 a week as equivalent to that amount in terms of income and as taxable accordingly from the principal's point of view it may seem only right that an expense which he is entitled to treat in his accounts as remuneration of the assistant should rank as part of the latter's income. However reasonable that view may be it is not sound in law. In one of the leading cases it was laid down many years ago that an advantage or benefit accruing by virtue of employment is not taxable in the hands of the employee unless it is received in money or in a form capable of conversion into money. This clearly covers the case of the provision of board and lodging which a man can benefit from but cannot sell or otherwise convert into money. It is, however, advisable to bear in mind the distinction between such a case as the above and one where the contract of service provides a monetary salary coupled with a condition that part of it be expended in a particular way. If for instance our correspondent's agreement had provided that he should receive £50 a

month but should reside under Mrs. Bardoll's roof and pay her £15 a month for board and lodging, then he would have been liable to income tax on the full £30 per month. It is a point which prospective assistants or their principals might keep in view when entering into a service agreement.

Income Taxed before Receipt

"V V V" explains that in declaring his private income, he gave the amount for the year ending December 31st, 1927, and has now received a letter requesting detailed particulars for the year to April 5th 1928 for his own and his wife's taxed income.

It is not quite clear by whom the request is made, but assuming that it is made by the authorities dealing with super tax we fear that our correspondent must comply. Where income of that kind is concerned, April 5th is the correct for naming date—the choice of December 31st or any other date applies to professional earnings. The authorities have no special authority to ask from what source "V V V's" daughter obtained her £400 capital, but a refusal to inform them that it represents gifts received in childhood—and thereby to dissipate any erroneous idea they may have—for example, that it represents accumulated earnings from some unknown source—is perhaps unwise.

Sale of Practice

"A M B" expects to transfer his practice as from August 1st next. His past returns have been calculated on the basis of cash receipts for the calendar year.

The precise method of adjustment depends to some extent on the decision of the Board of Revenue, who have some statutory authority in the matter, and as the question is a new one, we have as yet no definite guidance. It seems, however, probable that our correspondent's liability for the four months to August 1st, 1928 will be regarded as determined by four sevenths of his earnings for the seven months to August 1st, 1928, those profits being calculated on the cash basis as regards receipts. As regards the year to April 5th 1928, it is similarly probable that the revised liability—if an occasion for revision is considered by the authorities to have arisen—will be based on (1) the remaining three sevenths plus (2) one twelfth of the year to December 31st, 1927. "A M B" might usefully approach his local inspector of taxes to ascertain his views as to the basis and method to be applied.

LETTERS, NOTES, ETC

TREATMENT OF A SWALLOWED FOREIGN BODY

DR A. F. DOYLE (Wirksworth) writes: The following case is, I think, worthy of record since it provides an alternative treatment in the case of a swallowed foreign body, a very common occurrence amongst children. The patient, my own child, a girl, aged 4, swallowed a large gold sleeve link, one end of which was sharply pointed, I was very anxious on account of the risk of perforation of the gut. As an alternative to the steady and inelastic diet usually recommended in such cases I administered normacol in 2-gramm doses eight hourly. The foreign body was passed in thirty-six hours, without the least difficulty or pain, embedded in the gelatinous mass of normacol. This vegetable product I may add owes its laxative action to the fact that it swells to an enormous size on coming in contact with water.

TREATMENT OF PHTHISIS: A SUGGESTION

DR J. M. THORNE (Bletchworth) writes to suggest that in early pulmonary tuberculosis treatment by fresh air, rest, and clothing might be associated with the performance of incisions over one or more ribs the wounds being prevented from healing at once by the insertion of gauze strips thus promoting the free flow of lymph and serum. He thinks that the effect of healing wounds as in Albee's bone-grafting procedure, may be an important factor in the treatment of tuberculous foci, the formation of serous fluid with its antileptic content helping to check the progress of tuberculous disease elsewhere in the body.

SEA SICKNESS

FLEET SURGEON V. E. HOME writes: Dr. Elliott's letter on sea sickness (June 23rd, p. 1089) reminds me of old times. I was first sent to sea in a big steady battleship in the Mediterranean and suffered little, and was best treated with highly spiced food (cayenne pepper) after gastric relief had been attained. In a yacht where not being on duty I could treat myself as I chose. I found the hypodermic injection of 1/4 grain morphine a comfort, tiding one over till tolerance was attained. Later in a small gunboat in bad weather off the coast of Nova Scotia, I was very miserable one afternoon and promised myself that nothing should take me from the wardroom on the upper deck. However a marine wanted a tooth extracted, and I had to go down to the stuffy stateroom, inwardly protesting. The marine lost his tooth. I lost my sea sickness, and it has never come back so badly since, not even in the same gunboat hammering against the sea of the north-east trade on passage from Jamaica to Trinidad. Yet on our seventh day out an artificer complained

he had had no food since starting half an ounce of Worcester sauce put him right, also many patients subsequently. The service treatment for sea sickness is work and a good treatment too. As I found it, Lord Linnmouth in 1793 took the French *Cleopatre* with the *Symphie*, whose newly ruled crew were mostly laundries—Cornish minors. It was noted that during the action they forgot their sea sickness, but that they relapsed when the fighting was finished.

NEWSPAPER MEDICINE.

MR. BASIL HUONIS D.S.O. I.R.C.S. (Bradford) writes: Is not it time we called a halt to certain articles relating to health and disease which are appearing almost daily in the public press? These effusions nearly always involve mention of this name and opinions of some physician or surgeon who may or may not be known to the general public. The *Daily Mail* of June 19th contains a leading article emphasizing the views of Sir William Arbuthnot Lane on the method adopted by the Chinese in coping with illness. To quote a few lines: "The system of calling in the doctor when a breakdown occurs with the possibility of all the heavy expenses of operations, nurses, and nursing homes is one which as Sir William says may cripple for years the financial position of those who are in moderate circumstances. The alternative system avoids much of this heavy expense, and is specially welcome to the medical profession. Were these the views of Sir Arbuthnot Lane when he was in his hey-day as an operating surgeon, or are they his views of more recent years, or are they merely the *Daily Mail's* views of his views? Does the last sentence imply that the alternative system would be more welcome to the general practitioner when the surgeon's interference could be dispensed with? This would be, of course, the ideal."

POSSIBILITIES OF ORAL INFECTION

MR. A. T. SAWDAY F.R.C.S. Ed. (Dorset) writes: We hear much of the effects produced by organisms which enter the body via the mouth. I wish to draw attention to two factors, both remediable, which are possibly of no little importance in the spread of disease. It is a lamentable and disgusting fact that 99 out of every 100 shop assistants put their fingers to their mouths before picking up wrapping paper, and indeed in many cases before handling articles of food. Considering the prevalence of oral sepsis this widespread habit cannot fail to infect food with streptococci and other organisms and is possibly a factor in the spread of tuberculosis. The handling of food in shops at all is entirely undesirable and could easily be obviated by the provision of suitable tongs for this purpose. Another means by which disease may be spread is the use of infected spoons and forks. These receive a very perfunctory cleansing, which would be considered entirely inadequate for a spatula or other instrument used in the mouth. They could easily be boiled and I look forward to the time when all respectable restaurants and houses hold will keep a sterilizer for this purpose. Nails with metal handles could be similarly treated, but as they do not (or should not) enter the mouth they are of less importance. The spread of syphilis by infected spoons and forks is a very real danger.

TREATMENT OF CANCER BY INJECTIONS OF PERITONEAL FLUID

DR SIDNEY PHILL (Melbourne Australia) writes: In your issue of February 4th (p. 204) appeared a letter by Dr. J. B. Tomblason describing two cases of inoperable cancer greatly benefited by injections of blood or peritoneal fluid subjected to this tungsten ray lamp. In the hope that others will try the method I find I record the following case. The patient, aged 52, was found at operation to have an inoperable carcinoma, involving almost the whole stomach. When I saw him he could just swallow a few teaspoonsful of liquid and retain only a very little. His weight was 12st 8½lb on March 22nd when he received his first injection, on April 24th it had fallen to 11st 4½lb after the second injection. He was feeling better and taking more food. He had a distinct feeling of well being and his complexion was becoming pink instead of the previous very earthy colour. On May 21st, when he had his fifth injection his weight was 11st 8½lb. He was eating two eggs and a plate of bread and butter for breakfast and vegetables for dinner, could take a pint bowl of bread and milk at a sitting, eat a banana, take a glass of claret and enjoy a cigarette. From being hardly able to crawl he can now walk about for the best part of the day without fatigue. He has gained 4½lb in the last month and has had six teeth extracted in that time, two at one sitting and four at the other, which in his previously weak condition would have affected him seriously. He is retaining all his food now, but about once a fortnight he brings up some bile. What is going to be the end it is impossible to say, but I will report later.

CORRIGENDUM

DR C. MERRIN EYTON asks as to a correction mistake which occurred in the typescript of his memorandum published on July 7th (p. 14). The title should have read: "A case of musculo-cutaneous nerve paralysis."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 48, 49, 52, 53, and 54 of our advertisement columns and advertisements as to partnerships assistantships, and locum tenentes at pages 50 and 51.

A short summary of vacant posts notified in the advertisement column appears in the *Supplement* at page 20.

Observations

ON

NASOPHARYNGEAL EPIDEMICS
IN PUBLIC SCHOOLS *

BY

J ALISON GLOVER, OBE, MA, MDCANTON,
MRCP, DPH

Certain semi isolated communities, which are under strict control, seem to be designed for epidemiological study, and of these the public schools of England offer a unique field for observation. Few communities are more comparable and homogeneous in the age distribution, in the nationality, and in the nurture of the individuals comprising them. Yet, with the exception of the classical work of Clement Dukes, little systematic epidemiological work seems to have been carried out with this matchless material.

Surgeon Commander Dudley has, however, shown what can be done with somewhat similar material, and his two reports on the Royal Naval School at Greenwich, based largely upon the careful records of Surgeon Captain P. M. May, R.N., and published by the Medical Research Council, are, I think, even more important contributions to school epidemiology than Dr. Clement Dukes's studies at Rugby.

As early as 1905 Dukes showed that the public schools were suffering an increased number of infectious diseases, this was largely due to the greater care exercised at home and at preparatory schools in preventing infectious disease, and to the consequent greater proportion of boys who reached public schools unprotected by previous attack. There is, I think, a general impression that a further post-war increase has taken place. Other factors may be concerned in this post-war increase, such as (1) the greater prevalence of influenza since the epidemic of 1918, (2) the great increase in the number of boys sent to public schools since the war, causing overcrowding in classrooms and dormitories, and perhaps (3) the greater attention paid to what we may term (with Dr. Simey) "febricula."

I think all agree that most of the infectious diseases now prevalent in public schools are spread by nasopharyngeal or "droplet" infection, but I doubt if we all realize the enormous proportion of the total illness caused by direct nose-to-nose and mouth-to-mouth infection. The accompanying diagram shows the number of boys

Chart showing the large proportion of admissions for diseases usually conveyed by nasopharyngeal droplet infection to total admissions for diseases of all kinds. Shaded portions—droplet infection; black portions—all other diseases and accidents.

all boys ill enough to go to bed being admitted direct to the sanatorium, this fact partly explains the somewhat high admission rates in this case.

Let us now divide the "droplet" infection into the several diseases. The figures are shown in Table I.

On the whole, the ordinary infectious diseases of child-

hood occur less than would be anticipated, although measles comes twice in the four years, whilst German measles comes only once, diphtheria is absent, and mumps, chicken-pox, and scarlet fever are absent save for one or two sporadic cases. The absence of scarlet fever is remarkable in view of the fact that the tonsillitis at this school has been shown bacteriologically to be due mostly to infection by haemolytic streptococci, often of scarlatinal type.

Influenza, on the other hand, occurs in epidemic form in three out of four years in the Lent terms, and once as "gastro" influenza in a Christmas term. For comparison I will refer to a diagram from Dudley's statistics of the Royal Naval School, showing a somewhat similar epidemic prevalence of influenza, whilst there is a fair amount of tonsillitis, which was so prevalent at "X" (it must be noticed that tonsillitis has only been recorded from the summer term of 1916). There are several interesting differences: scarlet fever and diphtheria appear in epidemic form, but measles and chicken-pox are almost entirely absent (nothing under 1 per cent is shown) and German measles appears once, and then with an attack rate of only 5.5 per cent. This comparative absence of measles, German measles and chicken-pox may perhaps be explained by the fact that the Greenwich boys come from the public elementary day schools instead of from private boarding preparatory schools, and so probably have had most of these diseases before their entry at Greenwich, usually at the age of 12. The heading "feverish cold, chill, etc.," is apparently not recorded in the Greenwich statistics.

Dr. Dukes's Rugby statistics from 1871 to 1904 (*Health in Schools*, p. 467) have many points of interest, which include the absence of influenza before 1890, and even after that year the comparatively small size of the attack rates for this disease. Compared with Greenwich, the almost biennial visitation of measles, the frequent appearance of German measles, and the much greater prevalence of mumps, which all tend to offset the comparative absence of scarlet fever and the complete absence of diphtheria, are noticeable. The celebrated "fourth disease" appears in history in 1900.

Returning to the "X" statistics (Table I), large proportions of admissions are due to the following: (1) influenza (28 per cent), (2) feverish cold, chill, pyrexia, and bronchial catarrh (15 per cent), (3) tonsillitis 20 per cent of all admissions for the four years under review. The three added together and compared with Simey's published figures for "febricula" at Rugby (which term he uses to include all three), even after allowing for the absence of house sick rooms at "X" show an increase, due in part to a persistent infection with haemolytic streptococcus, which has been endemic at "X," but partly due, I think, to the three factors already suggested.

Some apparently regard it as almost impracticable to distinguish between epidemics of influenza and those of febrile colds, but we should try, though difficult often arises

Communicated on June 22nd 1928 to the Section of Epidemiology and State Medicine of the Royal Society of Medicine.

* Most of my information is confidential; the names of schools are given only when statistics are quoted from published work. I am thus unable to give the names of the many ladies and gentlemen to whom I am indebted for information but whose help I very gratefully thus acknowledge.

THE COMMON COLD

Dr Lempriere¹ states that colds and feverish catarrh account for 25 per cent of the admissions to the sanatorium—excluding epidemics of influenza. This agrees with the figures of the causes of absence for six public elementary schools in Sheffield, where 30 per cent of the attendances lost on account of illness were due to coughs, colds, bronchitis, etc. These figures covered a period of eight weeks in February and March, 1921, and showed that 80 per cent of the absence was due to illness, confirming the opinion that in public elementary schools roughly 10 per cent of school time is lost owing to illness. In Sheffield 10 per cent of the sick absence was due to zymotic diseases, 6.7 per cent to contagious diseases, and 30 per cent to coughs, colds, bronchitis, etc., while 3.8 per cent was due to sore throats. The period in question was not one of influenza prevalence in Sheffield.

Dr D. K. Brundage² has recently published a valuable paper analysing the sickness records of the Edison Company of Boston for the ten years ending December, 1924, and showing the comparative importance of the common cold and the other respiratory diseases in producing disability in adults.

These duration figures correspond fairly with figures in English public schools: the usual time in sanatorium for influenza cases being about ten days (1925, 10.35 days, 1926, 11.78 days, 1927, 9.36 days). Appended is a table of comparison between the Edison experience and that at "X."

Annual Experience per 100

	Edison Company Boston ten years ending Decem- ber 1924 all absences of one day or over due to sickness	X school four years ending December 1927 all admissions to sanatorium
Due to all diseases	104	95
Proportion due to re- spiratory diseases	54 per cent of all absences	68 per cent, or 83 per cent if measles and German measles be included
Days lost per absence for influenza	9.8	Approximately 10*

* Calculated from three years experience at X school.

INFLUENZA

We are often in doubt whether an epidemic of febrile catarrh is influenza or not, but, as a rule, when the real epidemic comes there is no doubt about it, the character of the epidemic is a better guide even than the clinical character of the case. The true influenza epidemic has an explosive character, which was early remarked upon. Sir Thomas Watson wrote, in 1833, "On April 3rd I saw the first two cases that I did see of the influenza, all London was smitten with it on that and the following day." A diagram was shown illustrating this explosive character in a school epidemic reported on by Dr Copeman.³ A similar explosive epidemic may be witnessed in a day school. In 1890, for example, half the boys of Chesterfield Grammar

School were attacked by influenza on the morning of Monday, January 27th.

High attack rates are very common, and in certain houses I have known the attack rate reach 95 per cent. There seems to be little or no correspondence between the height of the attack rate in an influenza epidemic and the prevalence of complications, such as pneumonia and otitis media. The pneumonia and otitis media are, in fact, secondary epidemics which may or may not occur. Thus, in 1890,⁴ on the training ship *Shaftesbury* 52 per cent of the boys were attacked with influenza in eight days, but no case of pneumonia occurred. In the following April (1891) there was another epidemic, only 25 per cent were attacked, but there were five cases of pneumonia. Dr Lempriere has said true influenza is beyond the control of the school medical officer, but that this ought not to apply to that most persistent endemic condition, pyrexia of unknown origin (P. U. O.).

We must now ask ourselves if there is any immunity to be obtained against influenza, does, for example, a previous attack, or the use of vaccine, imply immunity? In the great epidemics of 1918 and 1919 there seemed to be evidence that a previous attack did confer some immunity against one or more of the subsequent waves of infection. Thus, at King's College School, Cambridge,⁵ where 100 per cent of the boys were attacked by the epidemic in July, 1918, none were attacked in the epidemic of November, 1918, but 58 per cent were again attacked in March, 1919. A somewhat similar sequence occurred at Rugby.⁶ In the July epidemic of 1918, 37 per cent were attacked, in the November epidemic of the same year only 3 per cent, whilst in the March, 1919, 23 per cent were attacked, those who had the disease in the July, 1918, epidemic having practically the same attack rate as the school as a whole. These attack rates include only admissions to the sanatorium. Dr Simey,¹⁰ in 1922, considered that partial and temporary immunity is conferred by an attack of febrile catarrh against influenza, and by influenza against febrile catarrh. I am interested to know if he still holds this opinion, for in recent years it has seemed to me that no immunity is conferred by attack, but rather the reverse. In several epidemics recently there has been a tendency to a second attack only three or four weeks after the first, nearly 50 per cent of the boys in one house had definite second attacks in the same term in one epidemic which I investigated in February-March, 1925. Here is the experience of a preparatory school of fifty-eight boys. In the Christmas term of 1924, 52 per cent of the boys were attacked with influenza. In the Christmas holidays and the following Lent term twenty of those thirty who had been attacked in the Christmas term were again attacked by influenza, whilst of the twenty-eight who had escaped in the Christmas term fourteen, or 50 per cent, were attacked, so that the figures are against immunity being conferred by the first attack.

There is pretty general agreement that true epidemic influenza cannot be prevented by vaccines, but there is considerable difference of opinion as to whether the common or feverish cold, P. U. O., or febrile catarrh can be prevented,

TABLE II.—Influenza Attack Rates upon all Boys, Inoculated Boys, and Uninoculated Boys respectively

School Term and Year	All Boys				Inoculated Boys			Uninoculated Boys			Vaccines used and when given.

and whether the incidence of complications such as pneumonia and otitis media can be diminished.

As to the efficacy of vaccines in the prevention of influenza or febricula in public schools there is some little published evidence of a somewhat conflicting character. Dr Lempiere's¹¹ distinctly favourable observations at Haverbury, and Dr Attlee's,¹² at Lton, which are much less so. By the kindness of Dr Graham Forbes I have seen the summary of the evidence produced by a questionnaire sent out by the Medical Officers of Schools Association. In one or two epidemics, with the assistance of my colleagues Dr Griffith and Dr Scott, I have in two schools tried out special vaccines made from strains of organisms actually found at the schools in recent outbreaks. The evidence is conflicting and I think entirely inconclusive. One thing must, however, be remembered. The scales are weighted against vaccines by the fact that boys specially prone to influenza and colds are more likely to be vaccinated than boys who do not suffer from colds. In answering the questionnaire thirteen medical officers thought that vaccines did good and thirteen others considered them of little or no value. Strangely varying opinions were expressed. One medical officer, for example, says "Cases of catarrh are fewer than in previous years. I believe the inoculations have done much good." Whereas another says "No inoculations—only thirty-eight out of school, average four if the whole school had been inoculated low incidence would have been attributed to this. I do not consider prophylactic procedure justified by the figures." One observer considers that "vaccines are useless in the presence of chronic nasal trouble", whereas another observer states that he has "particularly noted good results from vaccines in adenoid cases." On the question of the prevention of complications, in one epidemic I had the opportunity of observing in the Lent term of 1927 a school of 450 boys among whom there were 163 cases of influenza (an attack rate of 36 per cent) and 15 cases of pneumonia, five (that is, all those which were typed) of which were due to Type I pneumococcus, whilst the attack rate of the inoculated (32 per cent of the total population had been inoculated with various stock vaccines) and of the uninoculated (68 per cent) was almost exactly the same. None of the boys, however, who developed pneumonia had been inoculated. In November, 1927, 71 per cent of the boys of this school were given a special vaccine* prepared in the Ministry's Pathological Laboratory, containing pneumococcus Types I and II, and although an outbreak of influenza occurred in the Lent term of 1928 with almost the same attack rate as in 1927 (36 per cent), no cases of pneumonia occurred. But the uninoculated 132 boys not only had a slightly lower attack rate for influenza (23 per cent) than the 319 inoculated boys, whose attack rate was 30 per cent (boys only inoculated once omitted), but they also, like the inoculated, had no cases of pneumonia. In another school in the same term, where 80 per cent of the total population had been vaccinated with a special vaccine of Pfeiffer's bacillus with pneumococcus Types I and II, prepared in the Ministry of

Health Laboratory from strains similar to those found in the previous year's epidemic, and administered in the previous November by the school medical officers, there was an almost complete absence of complications but that had been true also of two previous epidemics, in one of which stock vaccine had been used for 56 per cent of the total population, and also in much more severe previous epidemics of which we had no information as to the vaccinal condition. My own feeling with regard to vaccine against influenza and febricula is that the question is still entirely open, but if it is determined to recommend prophylactic inoculation against influenza, colds, and their sequelae, it is important that the course of vaccines should be given before the epidemic prevalence begins, preferably in November. This means that the injections should be given at school, and this requires a good deal of rearrangement of time tables, but my experience is that if the injections be left to the Christmas holidays they are as a rule deferred to the period of epidemic prevalence which usually begins about January 14th to 21st.

Bacteriological Findings

Drs Griffith and Scott have examined many nasopharyngeal and tonsillar swabs taken by me in school epidemics. At one school, "X," epidemics in four years were studied, the findings being set out in the following table.

Previous to the 1927 investigation a vaccine (Pfeiffer's bacillus with pneumococcus I and II) prepared at the request of the school authorities in the Ministry's Pathological Laboratory had been given in November, 1926—that is, before the epidemic season began—to 90 per cent of the boys.

It is interesting to note that at "X" in the Lent term, 1927, when some fifteen cases of pneumonia occurred in every class (five) in which the pneumococcus was typed, the type found was Type I. Type I is sometimes termed the "pneumococcus of youth."

PROPHYLAXIS OTHER THAN VACCINES AGAINST INFLUENZA

I am convinced that a more intensive prophylaxis against influenza and epidemic catarrh at the beginning of each Lent term (that is, during January and February) would well repay school authorities. Apart from the experience of most schools and all other experience, the Edison Company's charts, by Dr D. K. Brundage,¹³ show admirably the periods of maximum incidence in January and February, when it seems that our chief efforts should be made. I recommend a special letter to parents and a special form of certificate for the Lent term. I have not seen any health certificate that mentions influenza or feverish cold, and I suggest that the Lent term certificate might be printed on red paper to distinguish it, and should include a statement that the boy had not had a severe or feverish cold for a week prior to the day of return. I have seen three striking examples of the mischief that boys can do by returning to school prematurely after influenza. Here is one. One of two brothers contracted mild influenza at home in London on January 13th, 1925, the boy travelled by the ordinary school train on January 16th in a compartment with seven other boys, and had dinner in the dining car. The seven boys in his compartment (four

* This vaccine contained pneumococcus Type I 200 millions in 1 c.c.m. pneumococcus Type II, 100 millions. *Streptococcus haemolyticus* (Dochez) 60 millions. A form of tonsillitis due to infection with haemolytic streptococcus (Dochez) had been common in the November term of 1927. The following term tonsillitis recurred in epidemic form but Dochez's streptococcus was not identified, although several other strains of haemolytic streptococcus were.

belonging to his own house) and the boy who sat next to him in the dining car fell ill with influenza on the 18th or 19th. His brother, who may have been infected at home, became ill on January 17th. The boys of the house to which this boy belonged almost all suffered severely from influenza, the attack rate being 95 per cent, and many of the inmates had two attacks. The attack rate in this house was by far the highest of any house in the school.

Temperature Taking—I see no reason why the temperature of all boys should not be taken for the first three weeks of the Lent term, as is done in so many preparatory and girls' schools. Girls are certainly no less susceptible than boys, as is proved by evidence from conduction schools and from orphanages, etc., where boys and girls are under the same roof. Most of the evidence, including the Edison Company's experience before quoted, is, I think, that females are slightly more susceptible, yet the girls' schools appear to escape more lightly than the boys'. This is no doubt largely due to girls usually sleeping in cubicles, and that girls' schools are, as a rule, of more modern design than boys' schools, and partly to their being more under control than boys but it is also, I believe, very largely due to the practice of taking every girl's temperature every night and morning for the first three weeks of term and to the immediate isolation of any girl with a slight pyrexia. Why a scientific procedure like taking a temperature should be regarded as "coddling" or "fussing" I cannot say.

Isolation of Slight Pyrexia—The immediate isolation of any severe catarrh, or slight pyrexia, occurring within the first three weeks of term is of great importance.

Early School—I am strongly of opinion that there should be no work before breakfast during January, February, and probably March, though I should have no objection to a short sprint in the open air. Not only are boys' resistances, I believe, at a lower level before breakfast (admittedly a point difficult of demonstration), but the heating of the classrooms is usually at an even lower oblique—a point which can often be easily shown. I have seen classrooms which started the day at 36° F.

Nasal Douching and Sprays—Much previous experience with the meningococcus has rendered me sceptical as to whether good results follow the use of nasal douches or sprays. I have, however, met one schoolhouse in which their use appeared to be successful, and Dr O'Brien¹⁴ has expressed "a considerable amount of faith" in the power of an antiseptic oily spray to give a reasonable amount of protection. Gargling I regard as a harmless procedure in catarrhal conditions, and possibly useful in tonsillitis, but I should not recommend any form of nasal douche or spray as a routine measure for healthy boys, "nasal drill" is less objectionable, but I am not enamoured of it.

Baths—It seems probable that a proper skin reaction is one of our greatest defensive mechanisms against chill, and I strongly urge, with this end in view, that all hot baths or hot showers should be followed by cold showers. The Scotch douche (alternating hot and cold showers) might be well worth a trial as a prophylactic measure, especially for well-known susceptibles, and artificial sunlight might be worth trying for such boys as are known for their liability to colds.

Diet—It appears to me important that in the Lent term fresh fruit, particularly oranges, or fresh vegetables such as salads, watercress, etc., should be taken daily.

PREVENTION OF INFECTION

This is my main theme. Where does infection usually take place? There can be no doubt that by far the majority of infectious take place in the dormitories. I have investigated the possibility of infection in classrooms, dining halls, chapels, etc. In comparing class incidence in badly ventilated classrooms with that in better classrooms, I found that the attack rate in the poor classrooms was 38 per cent, in the good 32 per cent, but as the younger boys were, as a rule, in the poor classrooms, and the older classes in the better ones, the age distribution may have accounted for this difference, although it is not always the younger ages which suffer most heavily in influenza epidemics in schools.

In an epidemic which I investigated some years ago,

in a great public school, most of the infection apparently occurred in common rooms, which were used alike for meals, for preparation of work, and for the accommodation of convalescents from influenza, the windows of these rooms could be opened for only a few inches—conditions which not unmutually caused disastrous results, although the sleeping accommodation was admirable and on the cubicle system.

INFECTION IN SLEEPING QUARTERS

I am convinced that the main body of infection is conveyed in sleeping quarters. Where else do the infecting boy and the recipient of infection maintain close proximity for as long as the ten hours they spend in the dormitory? Again, the movement of air is less than during the day owing to the cessation of movement and the shut doors, and, unless the ventilation is really efficient, air pockets form (particularly in corners).

Many boys sleep open mouthed, the nasal filter is short-circuited, and the recipient receives the droplets of secretion containing the infection, particularly when sprayed by cough or sneeze through the open mouth. The way to minimize this infection is, of course, to keep the beds far apart with efficient cross-ventilation.

One of the things which have struck me in public and private boys' schools is the comparative crowding of beds which I have frequently encountered. The Royal Commission on Barracks which reported in 1861 insisted that there should be a distance of 3 feet between the edges of beds, 60 square feet floor space, and 600 cubic feet per bed.

The Board of Education in 1914, in issuing their Building Regulations for Secondary Schools,¹⁵ laid down the principle that there should be a space of at least 3 feet between beds, a floor area of not less than 65 square feet, and an air space of 700 cubic feet for each occupant, that ventilation must be adequate and that it is very desirable that a through current of air should be provided by arranging the windows on opposite sides of the room. Dr Dukes¹⁶ lays down the standard of 800 cubic feet. Nevertheless in my experience it is quite an exception to find 3 feet space between beds. I have found, for example, six beds in 27 feet of wall space, and thus in dormitories which were not cross-ventilated, and I have found dormitories ventilating into each other, and even into classrooms, dormitories with fifteen beds only 1 foot 4 inches between beds, with 52 square feet of floor space. In these crowded rooms direct bacteriological evidence of cross infection with haemolytic streptococcus was found, reminding one of the cross infection with meningococcus which one used to find in an overcrowded barrack room.

In the bed plan of a certain public school dormitory showing the grouping of cases of influenza (attack rate 50 per cent), it may be coincidence, but the beds are less than 2 feet 6 inches apart, ventilation is "end" and not "cross," and there is much "dead space." In a dormitory from another school the beds are 22 to 18 inches apart, the ventilation is poor, the total floor space only 48 square feet per bed, the effective floor space less. Eleven of the fifteen boys were swabbed, and five of the eleven were carrying haemolytic streptococcus, a carrier rate (non-contact) of 45 per cent. [Both of the plans were shown to the meeting.]

TONSILLITIS

I have investigated persistent epidemics of sore throat in three schools. In one the condition seemed due to non-haemolytic streptococci and there was a possible connexion with some sanitary defects, the infection at least cleared up immediately these conditions were rectified.

In the other two the infection was due to haemolytic streptococci. In one of these schools it was a long series of "dropping" cases of scarlet fever that caused attention to be drawn to the infection, in the other the tonsillitis was the feature of the cases which attracted attention, and there was only one sporadic case of scarlet fever, although many of the patients with tonsillitis carried strains of haemolytic streptococci which were serologically identified by Drs Griffith and Scott with strains obtained from cases of scarlet fever. In one term nearly all the cases examined carried a haemolytic streptococcus identical with a strain isolated in New York by Dochez, this strain is associated with scarlet fever, but not, so far as is known, with it in

epidemic form. It seemed possible at the school where the dropping cases of scarlet fever occurred that we were seeing a phenomenon ("the warning rise") rather similar to that seen in cerebro-spinal fever¹⁷ (and possibly in diphtheria)—that is to say that when the carrier rate (that is, the carrier epidemic) reaches a certain height (namely, 20 to 30 per cent) clinical cases may occur. The observations were, however, too fragmentary for this to be anything but a surmise.

In this school thorough "spacing out" of beds was carried out, together with improvement of the ventilation of the dormitories, and since then no more cases have occurred, six months having now elapsed.

This infection with haemolytic streptococci was in one or two instances, I think, definitely due to unsatisfactory conditions (overcrowding and poor ventilation) in sleeping quarters.

In connexion with tonsillitis the question of milk must be raised. I have only dealt with three samples of public school milk, and all were definitely dirty and bacteriologically bad. Other evidence seemed to show that the milk was not responsible for the tonsillitis, but, apart from this, I should not feel happy as a school medical officer unless either pasteurized or Grade A milk were in use. Pasteurization is best done on delivery at the school premises, as at Dartmouth.

I trust that medical officers of schools will forgive me if I suggest that there are great opportunities for interesting epidemiological study still unexplored in public schools. I suggest as examples

(a) The epidemiology and bacteriology of otitis media in relation to scarlet fever, measles, influenza, and febricula.

(b) Relative sickness rates of boys' and girls' schools, and of day and boarding schools.

(c) Relative incidence of droplet infections upon children whose tonsils have been enucleated and whose adenoids have been removed, compared with children who have not been operated upon.

The adoption or recommendation of some uniform system of medical records by the Medical Officers of Schools Association would be of great service. I hope that association will renew its activities, which have been so helpful to me in preparing this paper, and keep before its members their paramount duty of devoting as much time and thought to the preservation of health in schools as they do to the care and treatment of the sick pupils. I urge, too, that the modern boy or girl is an intelligent being, and should be treated as such, and encouraged to take an interest and pride in keeping fit. This can be attained without fussing or coddling; public opinion nowhere has greater influence than in schools, and it should be formed to regard the training of the body against infection as being as mainly on aim as its training to achieve athletic success or to endure fatigue.

SUMMARY

In the following summary of my points I advance them not as "conclusions," or as proved by my observations, but merely for convenience.

1 "Droplet" infections are responsible for at least 80 per cent of all sickness in our public schools. There is a well marked "danger period"—that is, the first two months of the Lent term.

2 It is probable that no immunity to influenza or febricula is conferred by previous attack, and evidence of the protective value of vaccines is inconclusive. There is, however, slight evidence that some protection may be afforded against complications, particularly pneumonia, the subject deserves more systematic study. Vaccines if given should be administered well before the beginning of the danger period, probably best in November.

3 Intensive prophylaxis during the first half of the Lent term would probably amply repay the trouble. It should include

(a) Special efforts to prevent boys returning to school after the Christmas holidays infected with influenza or febricula.

(b) Temperature-taking for three weeks.

(c) Immediate isolation of all pyrexias and catarrhs.

(d) No work before breakfast for at least the first six weeks of the term.

(e) All hot baths and showers taken during the day or after games to be followed by cold showers.

(f) Prevention of chill in watching matches, sports, etc.

(g) Increased provision for drying clothes, uniforms, and boots.

4 Infection mainly takes place in sleeping quarters, and proper spacing-out of beds and thorough "cross" ventilation in dormitories is of paramount importance. No school authority has done its duty to its pupils unless it has provided dormitory accommodation sufficient to allow of at least 3 ft clear space between the edges of beds and thorough and through ventilation. Until these essential wants are met the provision of properly sited, amply spaced, and "cross"-ventilated dormitories should take precedence of all building requirements.

5 Milk should be pasteurized.

[Dr Glover exhibited a large number of diagrams of these it has been possible to reproduce one only.]

TREATMENT OF BURNS AND SCALDS BY TANNIC ACID*

BY

W. C. WILSON, M.B., F.R.C.S. Ed.

BURNS and scalds are accidents of great importance in domestic and industrial life. They are often fatal, or inflict serious incapacity and deformity on those who survive. These serious consequences, together with the comparative frequency of the accidents, constitute a grave problem for the medical profession. The object of this paper is to give a very brief account of the more important studies which have been made in the subject, to review our present knowledge of it, and to inquire into the results of treatment. More especially the recently introduced tannic acid method of treatment is discussed and described, and the results in a series of personally observed cases are presented. For ease of description thermal injuries, either by scalding or by actual burning, will be included under the term "burns."

CLINICAL COURSE AND PATHOLOGY

A consideration of the clinical course and pathology of the condition is essential to a discussion of its treatment. It is customary to divide the clinical course into three stages, thus: (1) shock, (2) inflammation, (3) healing.

This classification is inadequate and misleading, and we prefer a division into four stages in the following way:

- I Shock ("initial or primary shock")
- II Acute toxæmia ("secondary or toxic shock")
- III Septic toxæmia
- IV Healing

Before proceeding to a consideration of these stages we shall refer briefly to the nature and causation of "shock." For a more complete account of the condition reference should be made to the numerous and exhaustive papers published by the Medical Research Committee.¹² The question has been reviewed by Cannon⁴ in relation to experimental traumatic shock, and the conclusion seems warranted that shock resulting from severe trauma, such as war wounds, is of two kinds—namely, "initial or primary shock" and "late or secondary shock," and these

* From the Surgical Clinics, Royal Hospital for Sick Children, Edinburgh, and the Clinic of Professor D. F. D. Wylie, Royal Infirmary, Edinburgh.

two conditions differ in causation, severity, and consequences. "Initial shock" is of nervous origin, is similar in nature to fainting or syncope, but longer in duration, and is due to a primary disturbance of the nervous vaso-motor mechanism. "Late shock," on the other hand, is due to the action of a toxic agent absorbed into the circulation from the site of injury. This toxin apparently is a product of protein disintegration at the site of injury. In a later section we shall show that the acute toxæmia ("secondary or toxic shock") which follows injury by burning is of similar origin. The term "shock" will be reserved for the condition of "initial shock." It appears more appropriate to designate the "late or toxic shock" as acute toxæmia, for it is essentially comparable in origin, pathology, and consequences with other acute toxic conditions.

STAGE I—Stage of Shock ("Initial or Primary Shock")

The main clinical features are prostration, subnormal temperature, pallor, low blood pressure with a small rapid pulse and cold skin. It arises immediately after the injury, and in the majority of cases is transient and slight in degree, and is of no serious significance. During the period 1913 to 1925 at the Royal Hospital for Sick Children, Edinburgh, 80 cases of burns terminated fatally. Of these, only 2 (2½ per cent) died during the stage of shock. In the case of burns the source of shock is probably widespread damage to the numerous nerve-endings in the skin.

STAGE II—Stage of Acute Toxæmia ("Secondary or Toxic Shock")

There is no doubt that this toxæmic phase is the real danger period in the clinical course, and is largely responsible for the high mortality of burns. It commences between six and twenty-four hours after injury, and in a large majority of fatal cases terminates in death within forty-eight hours from the time of injury. Of the 80 fatal cases previously mentioned 64 (80 per cent) died in the stage of acute toxæmia, and of these 50 (78 per cent) died within forty-eight hours from the time of infliction of the burn. Between the stages of shock and acute toxæmia there is usually an interval during which the patient looks well, even in cases of extensive lesions.

With the onset of toxæmia the temperature rises, often abruptly, and, more especially in children, it may attain remarkable heights—106° F. is by no means an uncommon level, and it may reach 110° F. shortly before death. The patient becomes restless, the expression is anxious, the pupils dilated, and the colour dusky or livid. Vomiting is a common feature of this as of other toxic states, and the vomitus is frequently "coffee ground" in character as a result of hæmorrhagic gastritis. The blood pressure is low, the pulse rapid and small, and the respiration rate increased. Death is usually preceded for a few hours by coma, convulsions, in our experience are rare.

It is obvious that since acute toxæmia is the most serious danger to life in injuries by burning a knowledge of its origin is of great significance.

Since Cumins¹ of Glasgow, in 1823, published reports of post-mortem examinations on a series of five fatal cases many theories have been propounded to account for the fatal issue. Such theories are now of historical interest only, the original references can be obtained from Bardeen's² admirable article.

Avdakoff,³ in 1876, was the first to suggest that a specific toxin entered the circulation after the injury. Since then evidence of a most conclusive nature has been forthcoming in support of his contention. We may cite as especially significant the work of Ajello and Panscandolo,⁴ who first practised experimentally a modification of "exsanguination-transfusion", that of Kijanzin,⁵ the parabiosis and other experiments of Vogt,⁶ the histo-pathological studies of Bardeen,⁷ McCrae,⁸ and Weiskotten,⁹ and the recent researches of Robertson and Boyd.¹⁰ These researches proved conclusively that a toxin appears in the circulating blood within a few hours of the infliction of the burn. The toxin is formed at the burned area, is absorbed into the

blood stream, and gives rise to the symptoms of acute toxæmia. The exact nature of the toxin has not yet been determined, but it is probably a product of protein disintegration occurring under the action of excessive heat,¹² and it is said to consist chemically of primary and secondary proteoses.¹³

Stages III and IV need not be discussed in this paper. In the collection of 80 fatal cases 12 (15 per cent) died during the third stage.

TREATMENT

The principles of treatment as indicated by the pathological condition in each stage will now be considered.

Stage I—In shock the main lines of treatment are to avoid undue exposure to cold and restore normal body temperature, to administer fluids, and to relieve pain. Pain is frequently severe, and for this drugs of the morphine group should be given to adults. The depressant effects of morphine or heroin in young children, however, must be borne in mind. Treatment of the injury by local measures is begun at the earliest possible opportunity, which is frequently during the first stage, and involves cleansing and dressing of the affected area. Experience has convinced us of the value of a light general anaesthetic when the areas are being cleansed.

Stage II—In this stage the primary indication of treatment is to prevent the absorption into the circulation of the toxin which is produced in the burned area. No antitoxin is available. To Davidson⁴ belongs the credit of showing that absorption of the toxin may best be prevented by inducing coagulation of the damaged tissue, thus rendering the toxin non-soluble. For this purpose he employed a local application of tannic acid and found that it minimized acute toxæmia or prevented it entirely.

Stage III—The treatment is that of a septic wound and need not be elaborated here. After primary tannic acid treatment, however, the management of this stage is considerably modified in these circumstances, since the application of wet dressings may be a source of danger.

Stage IV—The treatment in this stage is that of a healing sore.

PERSONAL OBSERVATIONS

Our series consists of 42 cases in children and 8 in adults, in which the principles of treatment outlined above were adhered to.

Details of Management

On admission the patient is put to bed at once. From the commencement of treatment the burned area is exposed to the air. No dressings are applied and the bedclothes are supported on a suitable "cage," inside which electric lamp bulbs are fitted. If shock is present, the foot of the bed is raised and artificial heat administered by means of the electric bulbs. Subcutaneous saline infusion is given if shock is severe. Morphine or heroin is prescribed for the relief of intense pain.

Cleansing—Having secured these arrangements, cleansing of the burned area is carried out immediately. Under a light gas and oxygen or other anaesthesia any blisters are opened and evacuated and all epithelium which is loose or raised by blistering must be completely removed, in order that the tannic acid may come into direct contact with the damaged tissue beneath. It is in this tissue that toxin formation and absorption occurs, and of it coagulation must be secured. The area is rapidly cleansed with ether, which exerts a drying and purifying effect and is specially useful if oily or greasy substances have been previously applied, for grease prevents effective contact of the watery solution of tannic acid.

Application of Tannic Acid—An aqueous solution of tannic acid (25 per cent in warm sterile water) is now applied. It must be freshly prepared for each application, since tannic acid in solution is rapidly changed to gallic acid, which has no power to precipitate or coagulate protein. The warm solution is sprayed on the affected areas from an ordinary nasal spray atomizer, and the parts are then dried by means of the electric lamp bulbs in the bed-cage. Spraying and drying are carried out at frequent intervals until all the burned area is covered by a thin

layer of brown coagulated tissue. In hospital practice we have found it most convenient to carry out the spraying at intervals of one hour, but, if practicable, as, for example, where a special nurse or attendant is available, the length of the interval may be considerably reduced. Coagulation may occur more rapidly in some areas than in others. So soon, therefore, as the desired result is observed in any part, that part should be protected by gauze during subsequent spraying. Application of tannic acid is stopped when a thin coagulum has formed, in order to avoid a too deep corrosive action of the acid. The risk of such an action is extremely slight when a weak solution is used, and can be entirely obviated by frequent observations of the area. The periphery of the burned area affected by a first degree lesion frequently shows a light chocolate brown after about eight applications. In the case of second and third degree areas a satisfactory coagulum is usually obtained after eight to twelve applications. Areas more deeply involved may require several further treatments.

Special Circumstances.—Special care is necessary in treating burns of the face. The eyes, the nostrils and the external auditory meatus must be protected during spraying by means of pledgets of moist wool, and in this region it is convenient to dispense with artificial drying. In any case if the temperature be above 101° F, drying the parts by artificial heat is both unnecessary and inadvisable. In some cases it is not practicable to use the spray method of application to the whole of the burned area, as, for example, when both front and back of the trunk are involved. We employ the method of the spray and free exposure for the more extensively affected area and the method of tannic compresses to the less extensively injured surface which cannot be simultaneously exposed. The details of the latter method are as follows.

Sterile gauze swabs very lightly wrung out of the warm solution of tannic acid are applied to the burned area and covered with a light layer of sterile wool and a bandage. The part is examined at the end of eight, twelve, sixteen and twenty hours from the time of the first application and when a light brown coagulum has formed the dressings are removed. To avoid the risk of pulling off the coagulum when removing the dressings they should first be moistened with fresh solution. Coagulation may not be uniform and it will be necessary in such a case to apply fresh compresses to areas which are not sufficiently tanned such areas being examined subsequently at intervals of four hours. When compresses are used the formation of coagulum is usually satisfactory in from twelve to twenty hours. The parts are then protected by a thin layer of dry gauze covered by cotton wool. We have also used this method of compresses in cases when the lesions were not extensive and the patients were not admitted to hospital.

Local Effects.—The immediate local effects of tannic acid treatment may now be enumerated. At an early stage of the process of coagulation frequently after the first application, pain is relieved and rapidly disappears. Application by the spray is painless and, indeed, can sometimes be carried out without rousing a sleeping patient. The entire affected area becomes covered by a thin brown, or brownish-black leathery coagulum, which when dry is perfectly insensitive and can be handled freely without fear of damage to it or of conveying infection to the underlying tissue. By virtue of its tough rigid character the coagulum acts as a splint and ensures the best conditions for the healing processes which are in progress beneath it.

Cure of Burned Area.—From the time when the coagulum has completely formed until it is removed no special local treatment is necessary. The bedclothes are supported and the areas exposed directly to the air. Several important points in the care of the area, however, require mention. As is well known, burns are, as a rule, more extensive than appears at first sight to be the case, and blisters frequently develop in areas which initially presented the characters of a first degree lesion. These are dealt with in the usual way and the raw areas sprayed with fresh solution. Occasionally fluid accumulates under the coagulum, and such a collection should be at once evacuated through an aperture cut for the purpose with scissors. Very little care is necessary in adults to protect the coagulum from trauma. As has been mentioned, parts subjected to pressure are covered with dry gauze, and in children recumbency is secured by tying down the limbs. If the perineum is

involved the bowels are regulated by rectal lavage, and nursing is facilitated if the patient lies in the prone position with a pillow supporting the pelvis. Soiling of the areas by urine may give rise to release of toxin and sepsis.

Treatment of sepsis in the third stage is the most difficult problem in the tannic acid method. Signs of a mild degree of infection, as evidenced by a discharge of a little sero-purulent fluid from the edges and some reddening of the surrounding skin, are occasionally seen at different parts of the area. In this case no active treatment is necessary, and the parts may with safety be left alone. Gross infection is fortunately a very rare occurrence, and is usually associated with the formation of sloughs in more deeply burned areas. In such a case a collection of pus may float up the coagulum, which can then be easily stripped off, or, should the coagulum continue to adhere firmly, it should be softened by vaseline and is then readily removed.

In no circumstances whatsoever should wet dressings be applied over the coagulum. We have observed on several occasions that, while the coagulum is present, and particularly during the first week, the presence of moisture, whether in an unopened blister or in dressings applied over the area, is associated with some signs and symptoms of acute toxæmia. Apparently in these circumstances the toxin, previously imprisoned in the coagulum, becomes released and gains access to the blood stream. Only when all coagulum has been removed may wet dressings be employed in the treatment of sepsis. On this point we have confirmed the observations of Davidson.

In the uncomplicated case the process of healing advances under cover of the protective coagulum layer. In superficial lesions, such as those of second and third degree, epithelium covers the raw surface completely in from eight to fourteen days. In deeper lesions the coagulated layer remains firmly attached to the subcutaneous tissue until loosened by the growth of granulations, usually between the eighth and sixteenth days. The coagulum should be left until it can be easily peeled off. Then an ointment dressing should be applied to any areas which are still uncovered by epithelium. The most satisfactory is sterile vaseline prepared in the following way. Squares of gauze or lint are laid out flat in a tin box along with a quantity of vaseline sufficient to ensure a generous impregnation of the material, and the whole sterilized in the autoclave. The squares can be removed one by one as required and applied directly to the area.

Lastly, the tannic acid method can be commenced as late as seventy-two hours from the time of injury, whether or not other methods of local treatment have been previously used. After this period the toxæmic danger has largely passed, and in the untreated case frank sepsis will be manifest. The lesion should then be treated as an infected wound.

GENERAL TREATMENT

Abundant fluids are given. Oral administration of fluids is, as a rule, sufficient, since toxæmia is mild or absent. In the severest cases, where a considerable quantity of toxin enters the blood stream before coagulation of the injured tissues has been effected, the procedure of "exsanguination-transfusion," as recommended by Robertson,¹⁴ is a valuable accessory method of dealing with the toxic state. A quantity of toxic blood is removed from the patient by bleeding, and is replaced by an equal, or slightly greater, quantity of fresh blood from a suitable donor. We found that removal of 120 to 150 c.c. in an infant and of 250 to 300 c.c. in a child of 3 years, was sufficient exsanguination. In an infant exsanguination and transfusion can easily be carried out by puncture of the superior longitudinal sinus through the fontanelle, preferably with a special needle, described by Dott.¹⁵

In young children, and especially in infants under the age of 1 year, it is of the utmost importance to estimate the temperature frequently. If toxæmia is severe the temperature may rise rapidly to 106° F or higher, and, as a consequence of this high temperature, death will shortly ensue unless active measures are taken to reduce it. Personal clothing and, if necessary, the bedclothes, should be lightened or removed, and tepid sponging may be required. Artificial cooling is a life-saving measure in

these cases. In our experience of the tannic acid treatment of burns hyperpyrexia has been almost unknown, largely because acute toxæmia is usually mild or absent, but also in part because the procedure of supporting the bedclothes on aengo and exposing the parts to the air assists natural regulation of the body temperature.

RESULTS OF THE INVESTIGATIONS

Our personal experience of the influence of the tannic acid treatment on the clinical course, the mortality, and prognosis in these cases will now be summarized.

Clinical Course

Stage I—It was almost invariably noted that application of tannic acid was followed rapidly by the relief of pain. From the first, therefore, this form of treatment promotes analgesia, and is associated with no discomfort whatsoever.

Stage II—The action of tannic acid in preventing or minimizing the absorption of toxic products from the burned area has been amply proved in this series. Of 50 cases only one died in the stage of acute toxæmia, and this unfortunate result was probably due as much to severe prolonged shock as to toxæmia *per se*. The incidence of acute toxæmia in cases treated by tannic acid before the onset of this stage may be shown in tabular form.

Treated before Onset of Stage II—40 Cases

	No. of Cases	Average Surface Involvement
No toxæmia ..	20	11 per cent
Mild toxæmia ..	16	12 " "
Moderately severe toxæmia ..	1	27 " "
Dangerous toxæmia ...	2	40 " "
Fatal toxæmia ..	1	27 " "

In the patient suffering from moderately severe toxæmia the burns were very extensive and coagulation proved slow. The general condition, however, gave rise to no anxiety. Dangerous toxæmia was the result of special circumstances. In one case the lesions involved 60 per cent of the total surface of the body. The other was a case, probably unsuited to the tannic acid method of treatment, in which the tissues of one limb had been broiled by slow heat while the patient was unconscious from carbon dioxide poisoning. The case of fatal toxæmia has already been mentioned. In 8 cases treatment was commenced during the toxic phase, and in all the symptoms and signs disappeared rapidly when coagulation of the injured tissues was effected. When it is recalled that 80 per cent of deaths from burns occurred in this stage with previous methods of treatment the significance and importance of these results will be appreciated.

Stage III—The incidence of sepsis in cases treated by tannic acid is shown in tabulated form.

Patients treated by Tannic Acid before onset of Sepsis—48 Cases

	No. of Cases.
No sepsis	32
Mild sepsis	12
Moderate degree of sepsis	2
Severe and fatal sepsis	2

The incidence of sepsis increases with the depth of the lesion, the presence of fluid, especially in blisters, which appear at the edges in the first few days, and the number of hours between the time of injury and commencement of treatment. In one or more of these factors was found the explanation of sepsis of mild or moderate degree. Severe sepsis was due to special circumstances, and occurred in the same cases in which severe acute toxæmia was observed. In both death resulted from sepsis.

Stage IV—The protection afforded to the growing epithelium and the splint-like action of the coagulum, as well as the low incidence of sepsis, have been important factors in minimizing scar tissue formation and preventing contractures. In only one case has skin grafting been necessary.

Mortality and Prognosis

The total number of deaths in the series was 7, of which only 4 were directly attributable to the injury. The remaining 3 deaths were in children, of whom 2 succumbed to virulent acute enteritis during epidemic periods and 1 to broncho pneumonia following whooping-cough. The death rate was, therefore, 8 per cent. Three children and one adult were

victims. Of the children, one died from severe shock, one from acute toxæmia after prolonged shock, and one from sepsis and exhaustion. Death in the adult occurred in the fifth week from sepsis.

It is obvious that a prognosis based on the extent of the area affected, relative to the total surface of the body, is very considerably influenced by the use of the tannic acid method of treatment. Observations by Fraser⁴ and Klauder¹⁰ indicated that in children the prognosis was bad when 11 or 12 per cent of the entire surface of the body was involved. In this series of 42 cases in children, 20 suffered from lesions involving 12 per cent or more of the total body surface, and of these 17 recovered. Moreover, in the great majority the clinical course was marked, not as in the past by severe and prolonged illness, suffering, and distress, but by an appearance of comfort, health, and well being from the commencement of the treatment.

CONCLUSIONS

1 Fifty cases of burns have been treated by tannic acid.
2 It has been shown that this method of treatment promotes rapid analgesia, there is complete absence of pain and discomfort while the coagulum is present, and during this time there is no necessity for dressing.

3 In many cases tannic acid prevents acute toxæmia and invariably lessens the severity of this phase when it develops. The prognosis as to life, especially in children injured by extensive burns, is thus greatly improved.

4 Sepsis is usually avoided in superficial lesions treated by the tannic acid method, and when sepsis occurs in deeper lesions it does so late in the course of the case and is of a mild degree.

5 Scarring is probably less marked than in other forms of local treatment on account of the protection afforded to the growing epithelium, the diminution of sepsis, and, hence, the minimization of granulation tissue which is the precursor of scar.

6 The death rate from burns in this series was 8 per cent, the figure compares very favourably with any which have been quoted from the results of treatment by other methods.

7 A prognosis based on the extent of the injury is considerably influenced by the tannic acid treatment. The outlook in children is not necessarily grave even if 40 per cent of the entire surface of the body is affected.

8 In view of the success with which this treatment has been attended we would recommend that its use be extended.

Tannic acid should form part of the armamentarium of the country practitioner.

In mines, factories, etc., it should find a place in the first-aid equipment, and its application by the compress method could be included in first-aid training.

Thus valuable time could be saved during transport of patients to hospital and the maximum benefits be derived from its life-saving properties.

Tannic acid can be conveniently kept in powder form, made up in packets containing 110 grains. One such packet dissolved in half a pint of water gives a 2.5 per cent solution.

I wish to thank Mr N. M. Dott and Miss Gertrude Herzfeld surgeons to the Royal Hospital for Sick Children, Edinburgh, and Professor D. P. D. Wilkie, University of Edinburgh, for the opportunity afforded for this investigation. To the resident staff of both hospitals during the period of investigation I am deeply indebted for assistance and co-operation.

SICKNESS ABSENTEEISM

A PRELIMINARY STUDY

BY

MILLAIS CULPIN, M.D., F.R.C.S.,

AND

MAY SMITH, M.A.

SICKNESS records in industry are becoming of increasing interest. Firms having a well-staffed and well-equipped medical department are naturally desirous of knowing the results of its operation, and it is disconcerting to some to find that the expense of the medical branch increases year by year, and *pari passu* the sickness absenteeism, while with others the reverse happens. Explanations vary, it may be that as the medical work becomes more effective, people are discovered who need treatment, but who in the absence of such a department would carry on until overcome by some serious disease,* or the other hand, workers inclined to sickness may take advantage of an inexperienced or overcautious medical officer.

The difficulties of obtaining adequate standards of comparison and, even when records are available, of interpreting the results have been discussed in a report to the Industrial Fatigue Research Board.

This paper presents the results of a preliminary study of the sickness records of a few firms. We have not attempted to deal with the data available to the various approved societies, we have studied particular firms in order to bring into relief individual problems masked in such data. The firms in question all had medical and welfare departments, and employed large numbers of men and women of the same age groups some were predominantly clerical, while others, besides clerical staffs, included factory workers, maintenance staffs, selling staffs etc. The figure used for comparative purposes was the average number of days lost through sickness per year per 100 workers. This is crude, but useful practically.

A study on this basis of about ten firms revealed some striking differences and suggested some serious problems. The range proved to be unexpectedly wide even within the narrow limits of this survey, and varied from two days per worker per annum in one firm to eighteen days in another. There is also a tendency for the remainder to cluster round those two extremes rather than to form a series. This phenomenon may be due to the limitation of the sample, we have no decisive evidence as yet.

In the case of three firms situated in different towns, each with at least four departments doing different classes of work, data were available for working out the monthly variations. Each department with two exceptions, averaged more than 500 workers. While the actual amount of sickness varied from firm to firm, and from department to department within the same firm, the seasonal variations were of the same type throughout. From about the beginning of March to the end of August, with slight individual variations, there is a gradual and significant decrease in the sickness, from August onwards there is a gradual increase. This variation is true of clerical workers, shop assistants, factory workers, workroom staffs, and general staffs—that is, engineers, transport workers, cleaners etc. In the case of those firms where medical diagnoses are available the increase is largely accounted for by influenza and allied disorders, the other ailments being fairly distributed throughout the year.

Comparing different departments within the same firm we find significant differences. In two large stores in different towns the workroom staff has less sickness than either the clerical or the selling staff. This is in line with the very low sickness rates in some factories.

Although as yet we cannot account for these differences, the following points are worthy of consideration.

1 It is frequently asserted, (a) that the factory and workroom make greater demands on the physical health

of the worker while the office demands more intelligence, so that the physically strong children go to the factory and the less robust to clerical work, and (b) that the clerical worker is more intelligent. This assertion, though decidedly popular, distorts many facts. Much factory and workroom work is quite light and physically unexacting and requires for its successful performance quite as much intelligence as do many forms of routine clerical work. Selection does however, take place in some schools in so far as the children who are better at examinations are often advised to take up clerical work, and in some factories we have interviewed workers who say they would have taken up clerical work had they been able to pass examinations. If it were true that those who could pass examinations were mentally superior and physically inferior to those who could not, then it might be that the factory and workroom selected the physically as opposed to the mentally superior or rather that the range of choice was affected by the absence of the brighter children who had gone to clerical work. The degree to which this selection is operating cannot be determined. Experience of workers in modern factories and in offices indicates that the difference in social class, education and intelligence is less than is commonly supposed. The clerical occupations it is true, may be attracting those who wish to be "genteel" and the mental conflict involved may add to the stress of life and play its part in determining sickness.

2 There may be greater satisfaction to the worker who is actually producing something or organizing its production, than to the clerk who records the results of the work of others. There is a considerable difference in experience between actually making 20 as against 200 articles, and recording in a column 20 or 200—a difference of time muscular activity, emotional excitement, etc. Certainly, so far as we have been able to get evidence the clerical worker tends as life goes on to become more dissatisfied with his work than does the producer. Some types are more likely than others to be thus affected.

3 With the shop assistant, as compared with the clerical and workroom worker, there enters another factor. Unlike the others, he is always in contact with an incalculable variable—namely some other person. Like the telegraphists and telephonists (both of whom have a high sickness rate) he is always adjusting to some other person. Even machines have moods, and raw material is not always up to standard but there is a limit to the possibilities of variation—a limit easily learnt by the machinist. The salesman however, has to be constantly adjusting to an almost limitless range of variation in his customers. This adjustment is a source of interest to some people, but certain types may find in it considerable strain which may find its expression in sickness.* The man or woman who reacts emotionally to the reactions of a customer, or who feels a sense of guilt if he fails to please or who worries at night over the work of the day, is more likely to break down as a shop assistant than as a workroom worker.

4 The borderline between sickness and health is a narrow one, and no observer can fail to see mental factors operating as well as physical. In one department of a large establishment were two rooms containing an equal number of workers, selected by the same tests and doing the same work. The head of one room was competent and mentally well balanced, the head of the other was nervous and difficult. Towards the end of a week during a mild influenza epidemic about 10 per cent of the workers of the one room were away and over 80 per cent of the other. It is true it might have been a chance occurrence, but in the light of the known effect of the particular persons in charge one may at least consider whether mental dissatisfaction had not played a part in determining the borderline people.

Types of authorities who are irritable, difficult, or somewhat overwhelming are not a negligible factor in determining absenteeism, particularly where the conditions of work involve practical security of tenure.

* Although this depends upon the assumption not yet established that attention devoted to trivial illness in adults does actually reduce the incidence of serious disease.

† The workroom staff is occupied in a wide range of activities comprising all branches of the sewing trades some engineering cookery etc.

* The selling staff might be supposed to be more in contact with infection than the workroom staff. When, however, it is considered that a worker in a factory or workroom may be in contact with hundreds of others the apparent difference is not so real. Nor is the proportion of infectious disease higher in the selling staff.

No one wants to keep a sick person at work, but prevention of sickness by any means available is a good thing. A "breakdown" may conceivably bear some relation to being "fed-up."

NATURE OF THE SICKNESS

So far we have considered the amount of sickness in some cases it has been possible for us to compare the medical diagnoses. Such diagnoses would in all cases be made by a large number of different panel doctors in different neighbourhoods, so that no one doctor's finds of nomenclature can be represented. We have only considered the diagnoses for people on long sick leave—that is, over thirty days. These show extraordinary diversity, not only in the gross amount of illness, but in its nature, as indicated by its diagnostic classification. Here are the details of cases involving long sick leave during one year in two firms.

Firm—F C		Firm—H W	
Days Lost	Diagnosis	Days Lost	Diagnosis
A 222	Sarcoma of ilium	A 278	Dyspnea and nervous debility
B 126	Motor accident	B 243	Pyrexia hydrocephalus
C 168	Pulmonary tuberculosis	C 181	Cough, high blood pressure, bronchial catarrh
D 98	Renal calculus operation	D 159	Influenza, influenza debility, nervous debility, nervous exhaustion
E 90	Pulmonary tuberculosis	E 156	Influenza and pleurisy
F 72	Appendicitis operation	F 140	Rhinitis
G 48	Cold, abscess of thigh	G 124	Nervous debility
H 43	Duodenal ulcer operation	H 123	Nervous breakdown
I 42	Influenza	I 109	Cardiac and nervous overstrain
J 38	Motor accident	J 105	General debility
K 33	Appendicitis operation	K 94	Debility
L 30	Influenza	L 92	Debility after appendicitis, influenza, and lambago

Average days sick leave per head per annum for men and women = 3.6

Average days sick leave per head per annum = 7.7 for men and 14 for women

It is clear that there is considerable difference between the two firms, though both do the same kind of work, and both employ numbers of men and women. H W is remarkable for the number of diagnoses of the type called nervous breakdown, whereas that type is absent in F C. With regard to these two firms we are able to throw some light on the difference.

In the course of an investigation into telegraphists' cramp² we had occasion to inquire into the type of person who got cramp, and were able to show that a majority of cramp subjects were of a psychoneurotic or "nervy" temperament—that is to say, that fear in some form played an undue part in their mental make-up. Continuing the problem of the incidence of the psychoneurotic temperament in the ordinary population, we have investigated sample groups of workers in several firms, among which are F C and H W. F C is remarkable in having a higher percentage of people free from psychoneurotic symptoms, and those with such symptoms had them to a lesser degree than any other group. This is correlated with the absence of psychoneurotic illness. Circumstances peculiar to the firm directed the attention of the medical staff to the importance of excluding the temperamentally as well as the physically unfit, and their success in that direction is verified by the results. A study of the medical diagnoses of H W showed that at least 51 per cent of the long sick leave was psychoneurotic in character. F C had also a large percentage of employees—84 per cent—who said they were interested in, and satisfied with, their jobs. H W had only 60 per cent who were satisfied.

So far we have not investigated any shop assistants, so we do not know to what extent, if at all, their relatively high sickness rates are due to the presence of psychoneurotics or to the nature of the work. It is

to be noted that although the variation within these few firms is great, both as to quantity and quality of the illness, yet all have good material conditions.

There are many problems in connection with this subject, some of which are in the process of investigation.

1. What part is played in the mind of the doctor as well as of the patient by the knowledge that there is practical security of tenure? There seems to be a tendency in such a case for a lengthier convalescence than where the position is risky, and that is not always beneficial.

2. What conditions affect the so-called nervous disorders? What occupations are most suitable for a "nervous" person, or will he break down in any occupation whatsoever?

3. In firms where there is a yearly increase in sickness, why should that increase be in disorders of a psychoneurotic type and not in those of an organic nature?

4. In determining the incidence of disease, what part is played by the knowledge that "compensation" may be obtained? Where this factor has resulted in an increased rate, what type of person has been affected? What is the effect of allowing full payment for a fixed number of days?

5. Does the size of the firm make any difference? In a small firm a worker often feels more important, and knows that his work falls on someone else in the case of absence, he therefore may hesitate to stop away for trivial reasons.

6. Do people who do not stay away for trivial illnesses actually develop more serious illness than those who do?

FULMINATING DYSENTERY IN A CHILD, CAUSED BY B. DYSENTERIAE SONNE

BY

W. HOWEL EVANS, M.B., CH.B., B.Sc.,

LECTURER IN PATHOLOGY, UNIVERSITY OF LIVERPOOL, PATHOLOGIST, ROYAL LIVERPOOL CHILDREN'S HOSPITAL, LIVERPOOL

SINCE Sonne (1915) first isolated and described the organism now generally associated with his name as a frequent cause of dysentery in Copenhagen, it has been very widely recognized in other countries. Thus its occurrence has been reported by d'Herelle, Franco (1916), Ohsell, Sweden (1917), Thjotta, Norway (1919), Mita, Japan (1921), Patterson and Williams, Australia (1922), South, Scotland (1924 and 1926), Channon, England (1926), and Nabarro, England (1927).

In several of the reports it is specifically stated that the disease commonly produced by the bacillus is of mild character. Thjotta states that the organism would be more frequently found but for the fact that the only symptoms are those of a mild diarrhoea which does not require medical attention. Fraser, Kinloch, and Smith (1926), in reporting 33 such patients in Aberdeen, none of whom died, state that while in exceptional cases the symptoms are of urgent description, in the "vast majority" of cases the disease is relatively mild compared with Flexner dysentery. The present case is therefore exceptional in regard to the severity of the symptoms and the rapidity with which death was brought about.

The patient, E. B., aged 10, was a strong and apparently robust schoolboy. He went to school as usual on the morning of September 8th, 1926, and at 10.30 a.m. vomited. He was sent home, and at 2 p.m. severe and frequent diarrhoea began, persisting until the evening, when the child appeared so ill that at 10 p.m. he was taken to the Royal Liverpool Children's Hospital. Death occurred at 3 a.m., September 9th—that is, sixteen and a half hours after the onset of the first symptoms.

On admission to the hospital the child was unconscious and dehydrated. Temperature 105° F., pulse 150. No stools were passed while in the hospital.

Necropsy, September 9th, 2 p.m. (eleven hours after death). The body was that of a well-grown boy of 10, but showing marked dehydration. The large intestine and lower part of the ileum were intensely congested, and contained reddish fluid and mucus. The mesenteric glands in the ileo-caecal angle were soft and red, and the Peyer's patches in the terminal part of the ileum were slightly swollen and red. The proximal part of the small bowel was practically unaffected. There was no ulceration in any part of the intestine. The thymus and other lymphoid tissues were normal for the age of the child.

Microscopically the intestine showed nothing beyond intense congestion and catarrh. Death was therefore due to an intense intoxication, there being no time for structural changes to be produced.

Cultures from the contents of the large intestine and from the ileo-caecal lymphatic glands yielded abundant and almost pure growths of the Sonne bacillus, but cultures from the contents of the ileum, spleen and heart blood were negative.

The bacillus had the following characters. On the MacConkey plate it formed rather large, opaque, rounded colonies, which at first remained colourless. Subcultures into the fluid sugar media gave the results tabulated below.

Lactose	Acid on 6th day
Glucose	Acid in 24 hours
Mannite	Acid in 24 hours
Maltose	Acid in 72 hours
Saccharose	Unchanged
Gelatin	No liquefaction
Indol	Negative
Motility	Negative

It was not agglutinated by Shiga, Flexner, typhoid, and paratyphoid antisera, but it was strongly agglutinated in the first subculture by a Sonne antiserum obtained by the kindness of Professor Cruickshank of Aberdeen. Later, at the request of Dr A. D. Gardner of the Standards Laboratory, Oxford, the strain was sent to him and its serological identity independently confirmed.

There are two difficulties in connexion with this organism which probably account for its infrequent recognition in the past. When first isolated the majority of the strains ferment lactose very late—six to ten days—and are therefore regarded as non-lactose fermenters. As they are not agglutinated by the usual standard antisera, as detailed above, they have been frequently regarded as "inagglutinable Flexner" strains. On the other hand, as pointed out by Thjotta, the strain may ferment lactose in two or three days, and may therefore not be distinguished from colon bacilli growing on the same plate. Final proof can only be obtained by serological tests, and fortunately the group specificity is very high.

Inquiries entirely failed to elicit the source of the infection. No further case occurred in the child's family or apparently in the school.

LIMITATIONS OF THE AGGLUTINATION REACTION IN THE DIAGNOSIS OF BACILLARY DYSENTERY

BY

J. MENTON, L.R.C.P. AND S.I.,
 COUNTY BACTERIOLOGICAL LABORATORY, LICHFIELD.

A RECENT outbreak involving 120 cases afforded an opportunity of further investigating the reliability of the usual routine agglutination tests in the diagnosis of bacillary dysentery. Standardized cultures and the technique recommended by Professor Dreyer were employed for estimating the agglutinin in the absorption tests; the procedures detailed in the Medical Research Council Special Report Series No. 51 were followed, and each absorption experiment was controlled by comparison with known dysentery strains. Blood samples were examined from 47 affected individuals, of which 19 were positive to the Flexner group and 28 were negative.

Ten cases, positive later, were negative at the first examination. The duration of disease at the first and second tests in these ten cases was as illustrated in the following table.

Table showing Duration of Disease at First and Second Tests in Ten Cases of Bacillary Dysentery

At Time of Negative Reaction		At Time of Positive Reaction	
Duration of Disease	No. of Cases	Duration of Disease	No. of Cases
3 days	1	5 days	1
8 "	3	16 "	2
11 "	1	30 "	1
12 "	1	32 "	1
15 "	2	33 "	1
16 "	1	34 "	1
17 "	1	38 "	2
		39 "	1

Predominant agglutinins for Flexner's bacillus Type V were present in the ten specimens, and ranged from 4 to 114 units per cubic centimetre of serum, five of them which showed 23 units or over were from patients who had been ill for thirty days or longer. One case of thirty-eight days' duration showed only 4 units, and the remainder reacted in the neighbourhood of 11 units. Agglutinins were also present for Type W, but to a less degree in 7 of these cases. Two of the sera showing 114 units to Type V contained 65 units to Type W. Of the three samples negative to Type W one showed 4 units and two 11 to Type V. Agglutinins to Type Y were present in all ten, and ranged from 4.4 to 8.8 units. Completely negative results were obtained with Sonne cultures and with Types X and Z. Absorption experiments pointed to a Type V infection, the reactions to the other types being attributed to the phenomenon of coagglutination. This diagnosis was supported by the isolation of Flexner's bacillus Type V from some of the cases in the same outbreak.

As the investigation proceeded it was noticed that all the specimens did not react in a similar manner to the first batch, and although a Type V culture was still agglutinated in the highest dilution, on translating the results into agglutinin units it was found that some of the specimens contained more agglutinins to Type W than to Type V, the suspension factor for the V culture was 11, while that for the W culture was only 1.9.

A Flexner bacillus was now isolated from the faeces of one of the cases, which proved on absorption to be Type W and not Type V. This point was verified by immunization tests. It was agglutinated by several of the positive sera, whether from the Type V or Type W cases, but without marked predilection, except that the serum of the patient from which it was recovered agglutinated it up to 1 in 5,000. This serum presented a peculiar anomaly—showing more agglutinin units to Type V than to Type W in the routine test, but absorption tests conducted on it with known V and W cultures were inconclusive. There was insufficient serum to repeat the investigation, and, owing to circumstances over which there was no control, a month elapsed before another specimen could be obtained. By that time the agglutinins had greatly diminished, and those to Type W were principal and predominant. This isolated bacillus only agglutinated the three stock standard antisera V, W, and Y up to a dilution of 1 in 125, but all the agglutinins were removed from the W antiserum by absorption with it, while the V and Y antisera were but slightly affected.

An important fallacy in the routine test was discernible in some of the early and late cases in which the agglutinins were not present in high amount. For instance, an established Type W infection reacted in late convalescence to Type V 1 in 25 and 1 in 50, and was negative to Type W in these dilutions, but reacted to it in lower dilutions. This effect was due to the great difference in the agglutinability of the respective cultures. The discrepancies which may arise when using dilutions of serum below 1 in 25 are recognized, but the example is tentatively put forward to illustrate what may happen when working with cultures possessing widely different suspension factors.

Taking the total 19 positives, 10 worked out as a Type V infection, and 2 were established as due to Type W. There were probably other cases of Type W among the 7 remaining positives and the 28 negatives, but owing to difficulties in procuring repeat specimens, and the fact that the Type W infection was not diagnosed until late in the

epidemic, further investigations in this direction were hampered. The 7 remaining serums, though positive for the Flexner group, were equivocal as to type by ordinary agglutination methods, and the amounts of the serums did not permit of absorption tests.

In four instances bacilli showing the morphological and cultural characteristics of the dysentery group, but not agglutinating with any of the stock antisera except the patients', were isolated. One of these organisms was also well agglutinated by another patient's serum. None of the serums in this epidemic agglutinated Shiga cultures, and none of the principal bacilli isolated were agglutinated with Shiga serum. In a few cases typhoid infection was coincident with the dysentery, but the agglutinins of the one infection were uninfluenced by absorption with the other micro organisms.

COMMENT

It will be seen that one negative agglutination reaction does not exclude acute bacillary dysentery, and this remark applies much more to these infections than to those of the typhoid-paratyphoid group. In typhoid infections the appearance of agglutinins with a few exceptions is constant about the seventh or eighth day, but in acute dysentery they may appear earlier in a few cases, though in many instances they are much later. Sir Leonard Rogers¹ states that "agglutination may occasionally be obtained as early as the third or fourth day, but it is not until about the tenth or fourteenth days that a larger proportion of cases, such as 50 per cent, yield positive results, while by the third or fourth week as many as 82 per cent of successes have been reported." Keersmakers² obtained positive agglutination tests in 75 out of 170 affected cases. W. Moodie³ infers that agglutination may be delayed for several weeks, and is of little diagnostic use. The literature abounds with divergent opinions as to the value of agglutination tests, and one is obliged to judge by one's own experience. In the epidemic under review the tentative diagnosis of a Flexner infection was made on repeated agglutination tests from a fair number of cases, but while a main group diagnosis, such as that of Shiga or Flexner, can be arrived at by this means, it is obvious that agglutination alone is not a valuable means of distinguishing between the various types of Flexner's bacillus, and even when the varying agglutinability of the cultures are known and taken into account such procedures must be supported by isolation of the micro-organism and absorption tests.

The duration of agglutinins resulting from these infections varies enormously, and in some of the cases under consideration they had practically disappeared within six weeks of recovery. They may, however, last for years and cause confusion, but such persistent agglutination can be distinguished from that resulting from active disease by repeated estimation of the titre, when it will be found to vary very slightly, if at all, when resulting from an old infection which is not active.

The presence of different types of Flexner's bacillus in this outbreak is not unique. Difficulty has at times been experienced by some observers in fitting the causative organism into the present recognized types even by absorption tests. This difficulty was experienced in one of the cases, in another, from which a definite Type W bacillus was isolated, agglutinins to Type V appeared to be the most prominent in the patient's serum, and the absorption tests were inconclusive. This may have been a double infection, but the last word has not been said on typing, and it is quite likely that organisms can exist showing a mixture of the antigenic properties of the several strains at present recognized.

The difficulty of giving an outbreak a type designation may be realized by the experience of Amako,⁴ who recovered five different types from a local epidemic, but the organisms isolated in his outbreak were so far removed from one another as to include members of the main Shiga and Flexner groups, and their main means of separation was by cultural reactions. While this observer's findings support the possibility of multiplicity of types in the same outbreak the development and improvement of serological technique since the time of this investigation must not be ignored. Modern serological procedures show that cultural characteristics must take second place.

In this outbreak the occurrence of several types could be reasonably expected, since dysentery has been endemic in the institution for years, and there are probably several sources of infection.

With reference to the strength of the agglutination reaction which is deemed diagnostic the Medical Research Council⁵ states that the presence of 10 or more "standard agglutinin units" per cubic centimetre of serum in a male, and of 20 or more units in a female, is for all practical purposes diagnostic of acute bacillary dysentery infection caused by the bacillus agglutinated—that is, if old infection or previous inoculation can be excluded. The presence of 6 to 8 units in a male and 12 to 16 units in a female justifies a strong suspicion of dysenteric infection.

CONCLUSIONS

1 Owing to lack of any correlation between the day of disease and appearance of agglutinins a negative agglutination reaction, even if shown by several affected cases, does not exclude bacillary dysentery.

2 If the serums from a number of cases are repeatedly examined for the presence of agglutinins it is often possible in the event of positives to place the cases in the main Shiga or Flexner group, and such findings may be further refined by absorption tests on these serums with known dysentery bacilli, but for exact work isolation of the causative micro organism from the patient is essential.

3 The possibility of the multiplicity of types of Flexner's bacillus in an outbreak is again established, but it has not been settled whether the lack of correspondence between the agglutinins as found in some of the patients' serums and the type of bacillus recovered from the faeces was the result of a double infection or the outcome of the close relationship of the W and V strains. The possibility of intermediate strains must also be borne in mind, but further work in this direction is necessary.

My thanks are due to Mr. F. W. Duke for the assiduous manner in which he helped in this investigation.

PATHOGEN SELECTIVE CULTURES AS AN AID TO THE DIAGNOSIS OF INFECTIVE FOCI *

BY

D. CRONIN LOWE, M.B.E., M.B., B.S. LOND.,
HONORARY PATHOLOGIST AND BACTERIOLOGIST TO THE SOUTHPORT
INFIRMARY, AND TO THE EYE AND EAR INFIRMARY, LIVERPOOL.

(Abridged)

THE bacteriological examinations carried out in this work do not refer to findings in acute infective or septic conditions, in which the causal organism is indisputably present in the pathological material and frequently isolated in pure culture, but to the more difficult matter of attempting to determine in a subacute or chronic case if any bacteria pathogenic to the patient are present in the specimens examined. In the bacteriological overhaul of any one case many specimens of possibly infective material may be examined in the search for the infecting organism. Improved technique and differentiating media have increased the possibility of isolating with greater precision organisms which may have pathogenic importance. This elaboration means that an increasing number of bacteria have to be considered in any case under examination, and the result of this has been to add to the difficulty of deciding as to which, if any, of such an assortment of isolated organisms are pathogenic to the patient and which are not.

Many serological tests are available to decide this question, such as agglutination, precipitation, haemolysin, and absorption tests, etc., but, except for special conditions, are either too elaborate or indefinite to be applied as a routine test in clinical bacteriological examinations. They all, however, indicate that serum or blood, preferably that

* Read before the Liverpool Medical Institution on March 29th 1928.

of the patient concerned, does contain some factor which is utilisable to decide this question of pathogenicity, if it can be applied practically.

Various workers have shown that natural immunity in animals is associated with the presence in their blood of bactericidal action to the organism concerned. **AGENT**

Black, Fowler, and Pierce conclude that an estimation of the bactericidal power of the blood "is the most dependable criterion of immunity in an animal."

In 1927 Solis Cohen³ of Philadelphia published a paper on "Accentuating pathogenic organisms in culture," which utilized this bactericidal power of blood as a means of differentiating the pathogenic from the non-pathogenic bacteria present in any specimen as far as the patient under examination was concerned, and called his method of doing this "Pathogen Selective Culture."

During the past year, with the hope of determining the relative pathogenic importance of organisms isolated from various foci in the same patient, this pathogen selective culturing method has been resorted to in over 600 specimens. As far as it has gone the findings of Solis-Cohen have been fully confirmed, and one or two other points which were not mentioned in his paper have been emphasized.

By this method an equal quantity of any specimen to be examined is inoculated, as far as possible simultaneously, on to suitable media on the one hand, from which, after incubation, will be obtained the ordinary direct or "A" cultures, and on the other hand into 5 ccm of the patient's own blood (freshly drawn), which, after incubation and subsequent subculture on to similar media, will provide the pathogen selective or "B" cultures, according to whether the patient's blood happens to be able to inhibit, or otherwise, any or all of the bacteria shown by the "A" cultures to have been present in the specimen.

The principal point of difference between this method of pathogen-selective culturing and others which attempt to obtain evidence of pathogenicity of the organisms present is that

1. The original material under suspicion is used as the inoculum of the patient's blood, and not the isolated bacteria from such infected material.

2. That the whole blood, and not the serum, of the patient is used.

3. It is important that equality of distribution of inoculum between the "A" and "B" cultures should be ensured, so that the results may be reasonably comparable, for it is obvious that the implantation of infected material into the patient's blood specimens should not be unduly heavy.

One has, therefore, as far as possible, standardized the emulsion of faecal and urinary deposits to be not greater than a strength approximately similar to a bacterial emulsion of 2,000 million organisms per cubic centimetre from which three loops are inoculated into 5 ccm of blood freshly drawn from the patient.

In the case of sputum, catarrhal discharge, and tonsillar and dental infective material the specimen to be inoculated has been thoroughly mixed in a few drops of broth, and from this equal quantities have been inoculated on to the direct "A" plates and into the freshly drawn blood. An analysis of 400 specimens shows that the results of the pathogen-selective cultures fall into one of the following five groups.

1. Similarity of results in the "A" and "B" cultures. This might be expected to be the most common result of such a procedure, and the opinion has been expressed by several critics that such findings would be usual. On the contrary, it has occurred in only 6 per cent of examinations in this series. The explanation of this is that the blood of the patients in this series of tests was deficient in normal bactericidal power and failed therefore, to inhibit any of the organisms present, thereby suggesting marked absence of general immunity.

2. A selection of more than one organism out of the many present in the specimen, as shown by the results of the direct cultures. This result was obtained in 30 per cent of the tests.

3. The selection by the "B" cultures of a single organism out of the several shown to be present in the

direct "A" cultures. This result was found in 35 per cent of examinations and constitutes the largest group of findings, which means that the most common result of culturing pathological specimens by this method is that the patient's blood will suggest that only one of the many organisms present is pathogenic to him and that the others are non-pathogenic, in that the specific bactericidal action of the blood is adequate to inhibit them.

4. That in 18 per cent of the specimens examined by this blood selective method organisms were isolated in the "B" cultures which did not appear in the direct "A" cultures. Solis-Cohen says of these findings—that "ordinary cultures may fail to contain the etiological factor in an infection," and suggests that these are either outgrown by the more luxuriant non-pathogenic organisms present in the specimen, or that the inhibition by the patient's blood of such non-pathogens has actually encouraged the growth of the pathogenic organisms, which are thereby readily recognized.

5. In the fifth group of findings, in spite of there being many possible pathogenic organisms present in the specimens as shown by the direct "A" cultures all of these were completely inhibited by the patient's blood cultures, suggesting that as far as bacterial contents of such specimens were concerned, the organisms were not pathogenic to the patient. This result obtained in 22 per cent of the examinations, and is of equal clinical importance to the previous positive findings, for when it comes to evaluating the pathogenic importance of the bacteriological findings of several specimens from one patient, it would appear reasonable to exonerate areas from which no pathogenic organisms can be isolated, and blame those in which such can be demonstrated as harbouring foci of infection capable of producing systemic infection in the patient concerned.

In classifying the findings of 400 examinations of various specimens into the five groups already detailed it is found that in over 50 per cent of the examinations pure single cultures of organisms pathogenic to the patient were differentiated by this method from the many present in the specimens, and in 88 intestinal examinations the striking result appears that all the organisms present in the faecal emulsions of 32 per cent of these were completely inhibited, suggesting that the intestinal flora, however important its bacterial content might appear to be, was not likely to be a source of infection to the patient concerned.

The same applies to the urine cultures, out of 20 cases showing bacilluria in carefully collected catheter specimens, in 14, or 70 per cent, the organisms present were shown to be non-pathogenic to the patient. This is quite in keeping with clinical experience, and while it is probable that in such cases the bacteria may be producing local irritation of the urinary passages, which requires local treatment, these organisms are not causal of systemic infection if such exists, and vaccine treatment prepared from such cultures (which are thus proved non-pathogenic to the patient) is not likely to be of any value, which probably accounts for the occasional disappointment attending vaccine treatment of such cases.

Several control experiments have been made to ascertain whether this pathogen selection would allow of accurate repetition, and equal quantities of the same specimen were planted into more than one sample of the respective patient's blood. The result was the selective isolation of the same bacteria only in each case. These findings appear to confirm the contention that the pathogen selection on the part of the patient's blood is associated with some want of specific bactericidal power.

The clinical importance of this method of bacteriological examination is the possibility of utilizing it to differentiate the pathogenic importance of organisms isolated from various areas which are suspected of harbouring a focus causing generalized infection. Space will only allow of three examples being given.

The examination of post nasal tonsillar sputum and faecal specimens in a case of chronic catarrhal asthma demonstrates that the patient suffers from infection of the respiratory tract, probably associated with some dental condition requiring treatment, but with no evidence of intestinal infection.

In a further case *asthma* alternated with urticaria and vaginitis, and the examination of sputum, urethral, vaginal, urine, and faecal specimens suggested an intestinal origin of the whole condition as probable, subsequent treatment seemed to confirm this conclusion.

A case of severe subacute infective arthritis gave a history of commencing as a result of puerperal infection accidentally contracted at a first confinement. Post nasal, tonsil, cervical, urinal, and faecal specimens were examined, and it was found that in spite of there being many organisms present in the ordinary cultures which might have been accredited as likely infective agents in such a case, the only strain that the patient's blood selected from them all was the comparatively simple *Streptococcus faecalis* from the faeces. It is, however, most likely that this would be the organism capable of infecting her at the confinement, and against which she had not yet regained an adequate immunity. It is further suggestive that this is so, in that she has proved disturbingly sensitive to the smallest doses of a simple autogenous vaccine prepared from this organism, but is slowly improving under this treatment.

In conclusion, the findings in over 600 examinations by the pathogen-selective culturing method confirm the opinion expressed by Solis-Cohen, that

1 Cultures as ordinarily made fail to differentiate organisms that are pathogenic for the host from those that are non pathogenic for him

2 Ordinary cultures may fail to isolate the etiologic factor in an infection in certain cases

3 In the pathogen selective culture the patient's fresh blood is used to inhibit organisms that are non pathogenic for him, thus permitting the free growth of organisms that are pathogenic for him

4 To these I would add, that this form of culture will also differentiate between foci in the same patient, and indicate those which contain organisms that are pathogenic for the patient and which are only of local infective importance

5 That such positive pathogen selective cultures when obtained from dental, tonsillar, or sinus material indicate the need for radical removal of such a focus of infection, if this is clinically possible

6 That when similar positive findings in intestinal specimens are associated with any clinical evidence of appendicular trouble the same radical attitude should be adopted

7 That negative pathogen-selective cultures suggest that the focus of infection from which the specimen was collected, while probably requiring local treatment, is not causal of systemic infection if such exists

8 That this pathogen-selective culturing method is only applicable to the bacteriological examination of cases in which some focal infection is causal of a systemic infection. Where the condition is a purely local infection, as occurs in many cases of chronic catarrh, cystitis, or colitis, the negative selective cultures will demonstrate this fact, and for such, if vaccine treatment is to be employed at all, the preparation should be made from the ordinary direct "A" cultures. Nor does this method apply to the preparation of ordinary prophylactic vaccines. It is essentially a means by which the selected pathogen represents the required antigen for the patient concerned.

The pathogen-selective culture method is therefore suggested as a valuable contribution to clinical bacteriological investigation, both as regards the presence of focal infection and as a guide to the treatment required for such a condition.

I wish to thank my colleagues of the Southport Infirmary and the Liverpool Eye and Ear Infirmary and the many clinicians who have allowed me to examine their cases by this method, also I wish to express my appreciation of the detailed and accurate work of my two assistants Mr. P. H. Osmond and Mr. L. H. Bennett which has added value to the conclusions drawn from these pathogen selective cultures.

A CASE OF PERTHES'S DISEASE OF THE HIP

BY

T. GARIFFLD EVANS, M.D. LOND., D.M.R.F. CAMB.,
PHYSIO-THERAPIST, CARDIFF ROYAL INFIRMARY

The patient in the case here recorded was a boy, aged 8½ years, who attended for examination on June 20th of this year.

The family history is good. He has a brother aged 5, and a sister aged 4, both of whom are fit. His father and mother also are well. There is no history of a similar condition in any other member of the family.

History of Present Condition.—His mother states that eighteen months ago, while running and playing about, he strained his left thigh and complained of pain in his left knee, and limped a little. He was kept resting in the house for a week, and had massage. At the end of a fortnight he appeared quite well again. Three weeks ago he stumbled over a molehill, and has complained of pain in the left thigh and knee ever since, and the limp returned. Some nights the pain has been severe enough to make him cry. Eight weeks ago he walked a distance of two miles, and the pain and the limp have since been worse.

The general condition of the patient on June 20th was good. He is a little undersized for his age. He walks with a definite limp on the left side, but he is able to walk and even run about with comparative ease. His mother states that he complains of pain around the knee and over the middle of the thigh in front. There is a quarter of an inch wasting of the left calf, and three-quarters of an inch wasting of the left thigh. No definite shortening of the left lower limb could be made out. While resting on the couch it was noticed that the left thigh was held slightly flexed and rotated outwards. Marked muscular spasm could be detected on manipulating the left hip, but the patient did not complain of any pain, and appeared quite cheerful. Flexion and extension of the hip were good, but definite limitation, though slight in extent, could be made out on careful examination. Abduction and external and internal rotation of the hip were very limited.

X-Ray Examination.—The x-ray appearance of the left hip-joint, as shown in the radiograph, is typical of Perthes's disease. The epiphysis of the head of the femur is much flattened and elongated, it appears to creep over the outer part of the neck of the femur. There is x-ray evidence of fragmentation of this epiphysis, the normal single ossific nucleus being broken up into numerous nuclei, which vary in density and shape. Towards the centre of the epiphysis can be made out a large and markedly denser bony nucleus, and on either side are tiny nuclei scattered irregularly. When compared with the normal

MEMORANDA

JULY 21, 1928]

side it can be seen that the outline of the acetabulum on the affected side is distinctly irregular. There is definite increase in the vertical depth of the neck of the femur (general rarefaction of the neck can also be seen). The whole of the shaft of the femur shows rarefaction.

Treatment—Mr J. B. Hayercraft, who also examined the patient, was of opinion that complete fixation of the hip in plaster was not necessary, he advised that a walking calliper splint would give all the necessary rest to the joint and protection from weight-bearing.

Conclusion

The recognition of Perthes's disease as a pathological entity became possible only through x-ray examination. Practically all our information regarding it has been arrived at by radiological investigation. Previously these cases were not recognized, and were usually classified as tuberculous joints.

It is very probable that some of the cases diagnosed as osteo-arthritis of the monarticular variety occurring in adult life have been cases of Perthes's disease, and that the secondary arthritic changes have been due to using an injured joint.

In my opinion the case recorded, if examined a year and a half ago, would have shown changes in the hip-joint, and the prognosis would have been more favourable. The symptoms in this case are comparatively slight, but serve to bring into prominence the importance of an x-ray examination of any joint trouble in a child. I hope to examine this patient at six monthly intervals for several years, and at a later date to give an account of the changes that have taken place in the joint.

I am indebted to Dr William Murphy for his kind permission to publish this case.

Memoranda: MEDICAL, SURGICAL, OBSTETRICAL

AN UNUSUAL CAUSE OF PAIN AND HAEMATURIA

THE ultimate fate of a "buried" silk ligature is that it becomes encysted, extruded, or absorbed. The last result has only been observed in the case of very fine silk ligatures, such as the four "O" size. Inversion of the tissue in which this silk had been placed twelve months previously, with subsequent microscopical examination, failed to discover any trace of the ligature material.

It is very well recognized that any infection of a ligature will lead to its ultimate extrusion. In the case of an

Cystoscopy—The mucous membrane of the bladder was healthy. About half to three-quarters of an inch above the right ureteral orifice the ends of a ligature could be seen projecting into the bladder like a villous papilloma. The ligature was coated with crystals and the appearance is well shown in the beautiful drawing by Mr Thornton Shells. With a ureteral forceps used through an operating cystoscope the ligature was seized and removed without much difficulty. This was followed by a moderate amount of haemorrhage. In withdrawing the ureteral forceps the ligature was dropped in the bladder but was voided by the patient shortly afterwards. Since the removal of the ligature the patient has been quite free from pain, and has had no recurrence of the haematuria.

It must be very seldom that one has the opportunity of seeing a case similar to that described above, although I have removed from the bladder a calculus the nucleus of which was a silk or linen thread ligature. The patient in this case had had hysterectomy performed four years previously.

London W.

FRANK HARVEY, F.R.C.S.Fd

infected ligature near the skin surface, a "stitch" abscess results, but if the ligature is in proximity to a hollow viscus and originally included either the mucous or submucous coats then, if it becomes infected, it will ulcerate through into the lumen of that viscus.

In the case to be described the ligature must have been passed through the mucous or submucous coat of the bladder.

On July 5th 1926 Dr Churchill David of Camberley referred to me a patient who had had hysterectomy performed for fibroids in February, 1925.

History—The patient, a woman aged 49, stated that she had suffered from severe pain on micturition from the day of her operation. The pain was paroxysmal in character, worse after micturition with occasional haematuria. For six weeks after the operation the pain was very severe but after that time it became gradually less severe and almost entirely disappeared.

March 1925 when the pain returned and persisted. The patient stated that she suffered from an aching pain lasting from five to ten minutes after micturition. The urine on examination was smoky and microscopic examination showed many triple phosphate crystals were seen.

THYROID SIMULATING ABDOMINAL TUMOUR

The rarity of the condition to be described and its clinical features make it of special interest.

A male child aged 2 years and 5 months was admitted to Falkirk and District Infirmary with a history of progressive swelling of the abdomen of one month's duration. Three weeks before admission the child had fallen and bruised the anterior abdominal wall.

When first seen the child who was very well developed was sleeping peacefully. The respirations were slightly increased and mainly thoracic in type. The abdomen was markedly and uniformly distended. Palpation of the abdomen showed it to be neither rigid nor tender but on deep pressure a mass could be felt which resembled enlarged abdominal glands. The note all over the abdomen was tympanitic. There was some dullness and rales were heard at the bases of both lungs posteriorly. The pulse rate was 112 per minute and the volume good. There was no sign of bruising of the anterior abdominal wall. A provisional diagnosis of enlarged abdominal glands with broncho-pneumonia was made and medical treatment was prescribed.

The subsequent clinical history presented no features inconsistent with this diagnosis. There was no diarrhoea or vomiting and the temperature was irregularly febrile. On the second day in hospital fluid of a serous nature was withdrawn from both sides of the chest, a total of 20 c.c.m. being obtained. By this time the respirations had become very laboured and the child had to be propped up in bed. The abdomen was still much distended but there were no signs of free fluid. The patient given rapidly worse and died on the fourth day of residence in hospital.

At the necropsy there was no fluid in the abdominal cavity and the liver was fairly firm consistency and pale appearance. A globular mass of fairly firm consistency and occupying the mesentery of the small intestine. There was no mucous or fluid in the abdomen. Both lung were collapsed and there was much serous fluid in the cavities. Pale-coloured tissue resembling that found in the abdomen was present in the anterior mediastinum although the mass was not much larger than a normal thyroid gland. It was adherent to the pericardium and the diaphragm. The spleen and liver were apparently normal but a nodule of the same pale tissue was found in the cortex of the left kidney. Portions from the abdominal and mediastinal masses from a discrete gland in the mesentery and from the nodule in the left kidney were sent to the Royal College of Physicians, Edinburgh for the following pathological report was received.

Sections show the tumour to be a sarcoma (thyroidoma) with origin in the thymus (reticulum) with metastases to mesenteric glands and kidney. The tumour cells are large in parts and the picture in many respects resembles that of Hodgkin's granuloma.

It is interesting to note the fact that the clinical picture in this case was dominated by the abdominal mass due to lymphatic

spread, it is of interest to note the presence of a distant metastasis in the kidney, especially in view of the resemblances to Hodgkin's granuloma.

I am indebted to Mr Tennant and Dr Hunter for permission to publish this case and to Dr Simpson for confirming the history of the patient prior to admission to hospital.

Falkirk.

WILLIAM BROWN, M D Glas

TABES DORSALIS AND GUMMATA OF THE TESTES

THE following case presents certain unusual features (a) the association of tabes dorsalis with gummata of the testes, (b) the complete absence of findings for syphilis in the blood serum and the cerebro spinal fluid.

A man, aged 64, was admitted to St Paul's Hospital under Mr W K Irwin on August 19th 1927. He stated that a slightly painful swelling had suddenly appeared a week previously in the right testis and four days later in the left. The urinary symptoms, which were of a fortnight's duration were straining, slight dribbling, and incontinence during sleep. He had Argyll Robertson pupils, and there was some inco-ordination of the limbs. Romberg's sign was present, and there was marked hypotonia of the lower limbs. The outer borders of the feet and the ulnar borders of the forearms were insensitive to tactile stimuli, and there was extreme hypoaesthesia to pressure of the larynx and the testes. The epigastric and abdominal reflexes were present, but the cremasteric reflexes were absent. The plantar reflexes were flexor. All the deep reflexes were absent. The bladder reached to the umbilicus and contained 32 ounces of foul alkaline urine. Rectal examination revealed little if any enlargement of the prostate, which was soft and mobile.

No scar of a previous chancre could be detected on the penis. Both spermatic cords were thickened, the constituent structures being matted together. The left scrotum and testis were adherent, forming a firm mass—hot, red, and enlarged to the size of a large goose-egg. The opposite side was in a similar state. In addition there was present on the anterior aspect of the right scrotum a fluctuating area in the centre of which the skin had broken down leading to the body of the testis. On dilating the skin opening with forceps the base was seen to be yellowish and sticky. Both testicles were absolutely painless to pressure. There were no enlarged inguinal or lumbar glands. The temperature of the patient on admission was 100°F and the pulse rate 90.

The diagnosis made was tabes dorsalis and gummata of the testes. He was given 0.45 gram of novarsenobillon and 0.2 gram of bismuth. The bladder was slowly emptied and washed out with 1 in 10,000 silver nitrate solution, and this was repeated daily. The right testis was packed every four hours with gauze soaked in eusol.

On August 24th there was a distinct area of softening in the left testis, which by the next day had broken down giving exit to much foul pus. The appearance then presented was identical with that of the right side on admission, and similar treatment was adopted.

The laboratory reports were to the effect that the Wassermann reaction in the blood was negative and the cerebro-spinal fluid healthy. The Wassermann reaction of the blood repeated six days after the provocative injection of novarsenobillon was negative.

Injections of novarsenobillon and bismuth equal to the first given were repeated weekly. By September 1st both testes had become much cleaner and were healing rapidly, by September 20th healing was complete. The condition of the urine also improved remarkably.

The Wassermann reaction of the blood was tested for the third time on September 19th and was again negative. The cerebro-spinal fluid remained healthy. On September 21st Mr Irwin on cystoscopic examination found the typical appearances of atonic bladder as seen in tabes. There was no intravesical enlargement of the prostate.

The patient was discharged from hospital the next day.

I desire to thank Mr Irwin for his kind permission to publish this report and also to acknowledge my indebtedness for his help and advice.

EXTENSIVE EPITHELIOMA OF THE CHEEK AND LOWER JAW TREATED BY DIATHERMY

THE following case appears to be of sufficient interest to record, in view of the fact that growths of a smaller size are often pronounced inoperable.

A olergyman, aged 70, was sent to consult me on March 20th 1925. About eighteen months previously he had consulted his doctor on account of pain in the mouth on the left side at about the angle formed by the ascending and horizontal rami of the jaw but there was nothing to be seen or felt at the time of the examination. He said that some time later a small sore appeared but he did not consult his doctor again until two or three days before he was sent to me. During this time the ulcer had gradually extended until the condition at the time of

the examination was as follows. There was very slight limitation of movement of the jaw. When the mouth was opened an ulcer was seen extending over the cheek from the junction of the ascending and horizontal rami of the jaw to within half an inch of the angle of the mouth. It is edentulous, and the upper limit could be seen a little below the level of the upper alveolar margin, and from there it extended downwards and on to the outer aspect of the lower jaw. Clinically and microscopically the condition was malignant.

At first it appeared beyond the limits of any operation, but there were certain points which made me decide to use diathermy. The growth had not appeared till the patient was old (69) and although extensive it did not appear to infiltrate to any great extent. It had extended slowly and there was no glandular enlargement. The patient was in very good condition.

Operation.—The whole growth was coagulated with the button electrode and the coagulation was carried deeply on the jaw. In the anterior part the coagulation was carried out more lightly in order to avoid, if possible, making a perforation.

A month later it was apparent that a certain amount of growth remained, particularly anteriorly, and the whole area was again gone over with the button electrode and in addition the knife was used, criss-crossing through the tissues. When the sloughs separated a perforation about the size of a threepenny piece appeared close to the angle of the mouth, and radium was applied.

When he left the nursing home he went away to the Midlands and the surgeon who looked after him informed me that a sequestrum separated from the lower jaw and after that he healed rapidly. The hole near the angle of the mouth at first caused considerable trouble owing to the escape of saliva but a piece of oiled silk strapped over it gave considerable relief, and I proposed closing it later. I did not see him again till April, 1926 when there was no sign of a recurrence and the hole had become so small that it gave no trouble. He is still free from any recurrence and carrying out his parochial duties.

Reports of Societies.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS

THE summer meeting of the Society of British Neurological Surgeons was held in Edinburgh on June 8th and 9th, under the presidency of Mr WILFRED TROTTER.

Mr NORMAN DOTT opened the proceedings by performing an operation at the nursing home in Great King Street, when he removed an osteoma from the roof of the orbit by means of an osteoplastic craniotomy. Dr LOVIN TURNER gave an account of his work on the paths of intracranial infection, demonstrating the meningeal and vascular connexions, particularly those in relation with the nasal passages. In the afternoon Professor Sir L. SHARPEY-SCHAEFER reported a study of nerve section and regeneration in his own hands. This was followed by a discussion introduced by Drs TRAQUAIR and SINCLAIR on the relations of ophthalmology to neurological surgery, with special reference to visual field defects. Dr GRAHAM and Mr DOTT showed some cases illustrating this subject. Professor EDWIN BRAMWELL described a case of intracranial aneurysm and showed a specimen. The Society's dinner was held the same evening at the North British Hotel.

On Saturday morning a demonstration of radiograms of the skull was given by Drs WOONBURN MORISON and HOPE FOWLER. Dr Hope Fowler discussed the radiotherapy of intracranial tumours. Some of Mr DOTT's cases thus treated were shown. Professor D P D WILKIE contributed an account of a case of intracranial dermoid cyst, successfully operated on by himself, and a case of acoustic neuroma in which a cerebellar decompression operation had been performed. Professor JOHN FRASER showed a case of injury to the brachial plexus, associated with a fracture of the clavicle by direct violence, and a case of elephantiasis and trophic disturbance of a lower extremity in a child affected by spina bifida. Mr W W WAGSTAFFER read a paper on the incidence of traumatic epilepsy after gunshot wounds of the head, and gave figures of the frequency of Jacksonian and generalized epilepsy after these injuries.

A most instructive meeting was concluded by a demonstration of various kinds of cranial anomalies by Mr D M GREIG, curator of the museum of the Royal College of Surgeons of Edinburgh, in the beautiful hall of the College.

Rheubius.

RHEUMATIC DISASTERS

THOSE who took part in the Conference on Rheumatic Diseases at Bath last May must have felt aware that the success of the conference was due, not merely to the very signal hospitality of the City Council, but largely to the thoughtful preparation and plentiful hard work undertaken by the organizing committee. The same readiness to spare no pains is evident in the volume of the *Proceedings* of the conference, which has now been published.¹ The constituent addresses and papers together form an excellent survey of the subject of the conference, with a minimum of overlapping or padding, and the editor, Dr R G Gordon, is to be complimented on the fact that the work of the conference is presented to us in a form which enhances its scientific value and also makes, for many, a pleasing moment.

In our issue of May 19th we published full accounts of the individual contributions to the conference, and thus in noticing the volume of the *Proceedings* there is no need to refer to these again in detail, nor to rehearse the names of the many authorities whose views are to be found in this book. Rather does this seem the opportunity now that the conference can be reviewed as a whole, to try to see what lessons it has for us and for the future.

The scope of the conference included all conditions called "rheumatic," and it is evident that in one respect at least those who confined their attention to acute rheumatic infection enjoyed an advantage over others dealing with muscular and chronic joint conditions. At the least they had a "disease" to speak on, and when they used the term "rheumatism" everyone understood them. And here, though we digress, we cannot forget the pleasure of praising Dr Carey Coombs's paper on "The bacterial factor in the rheumatic infection of childhood." When heard in the rather hurried circumstances of the conference it was generally recognized as a little masterpiece and now, having read it at full length, it would be difficult to overpraise it. It is rare to find in medicine a writer who can unfold the drama of an infective disease in this way in a style so sure, so light, and so convincing and yet with such modesty that the last thing that strikes the reader is the amount of personal work upon which all is based.

Outside the group of acute rheumatic infection the term "rheumatism" was indeed allowed its fling not, we fear, for the last time. It may well be that the atmosphere of a celebrated spa is not a favourable one in which to attempt to restrict the use of a popular term, yet it would seem as though, at the conference, even the non-committal word "fibrositis" was almost forgotten. Taking the *Proceedings* as a whole, it becomes apparent that this meaningless nomenclature is now no little drawback, and that a real effort should be made to insist on a classification on more correct lines. Such would at present necessarily be very incomplete, but if started on the right lines expansion as accurate knowledge increases would not upset it. Another matter, not altogether dissociated from that of nomenclature, is the possible connexion between the true rheumatic infection and the various more or less chronic disorders still grouped as rheumatic. Very little light was thrown on this subject, important as it is, by the conference. It seems hardly to be doubted that there must be a chronic form of true rheumatism, yet at present we do not recognize it with any certainty, indeed, we do not yet know by what tests we are to attempt such recognition.

Perhaps it is not unfair to say that in the more chronic and crippling forms of "rheumatism" the matter of treatment claims attention more insistently than any other aspect of the problem and in this volume there are the experiences of many in the various forms of treatment in current use. The amount of attention paid by some of the writers to the influence of the endocrine glands and the skin is striking. It is not altogether clear on what grounds the endocrine "factor" is classed as among the causative

factors rather than as a secondary phenomenon. On this particular subject the amount of disagreement shown in the various papers is considerable.

England is the home of the "rheumatic diseases," and, we hope, of rheumatic research. It is gratifying that the meeting at Bath drew together not only workers and observers in this country, but also from the Continent and America. That the conference was a success and did good to the study of "rheumatism" we do not doubt. The volume of the *Proceedings* is of great value, for it shows us, as perhaps nothing else could have done, where there is agreement, where there is doubt, and where there is almost complete ignorance.

DISORDERS OF THE HEART

THE appearance of a posthumous edition of *The Sensory and Motor Disorders of the Heart*,² by Dr ALEXANDER BLACKHALL-MORISON, is sure to be appreciated by a wide circle of admirers. Those who are not able to accept his point of view will find in his work much that is stimulating and something to emulate in the constancy with which he pursued his investigations and the vigour with which he has presented his case. Unlike many books that appear from time to time, in this the reader will seek in vain for any suspicion of plagiarism. Where authors are quoted it is more frequently to contest their views than to accept unconfirmed their opinions. Dr Blackhall-Morison placed himself among the "neuralists" and while recognizing that they are in the minority as compared with the "muscularists" believed that the disparity will gradually be reduced.

The arrangement of the book is well defined. The opening chapters deal with the development of the heart and the nature of the cardiac musculature and innervation and the coronary circulation, many of the arguments being deduced from the author's observations in the embryo fish. The section on sensory disorders of the heart, dealing as it must with cardiac pain and the various forms of angina pectoris is well worth perusal by all who are interested in a branch of the subject which has attracted many of the great physicians of modern times. This section closes with a discussion of such surgical procedures as precordial thoracotomy and nerve section for the relief of pain, the latter of which the author considers unjustifiable. The section on the motor disorders is perhaps a little more difficult to follow as he tends to depart from generally accepted terminology, and likewise from many of the views generally held as to the basis of the disordered mechanism. In the management of the case however and its medicinal treatment the fruits of a wide experience are displayed.

While we are unable to agree with many of the views expressed or to accept the arguments upon which these are based the perusal of the book has supplied both pleasure and profit. It is refreshing to read a work in which the personality of the author is so clearly portrayed on the printed pages.

THE ART OF OBSTETRICS

Dr W G LEE the author of a book entitled *Childbirth*,³ died before completing its revision for the press and no one who reads his posthumous work can but feel deep regret that an original thinker, gifted with a rare power of clear exposition should have thus early been lost to medicine. His style is simple and so unencumbered with medical idioms and phraseology that, as his colleague who supplies the prefatory note remarks, "a layman with sufficient interest in the subject would find most of the book within his grasp." But it is not easy to discover the precise object of the book or place it in any definite category. The impression obtained from its opening chapter is that the author had struggled against certain tendencies, especially allowing the science of medicine

¹ *Proceedings of the Bath Conference on Rheumatic Diseases*. Bath: The Hot Mineral Baths Committee of the Bath City Council. London: IL & Lewis and Co., Ltd. 1928. (Demy 8vo pp xi + 292. 5s net 5s. 3d. by post.)

² *The Sensory and Motor Disorders of the Heart*. By Alexander Blackhall-Morison. M.D. FRCP. Second edition. Foreword by Sir John Rice Bradford. KCMG FRSE MD London. Baillière Tindall and Cox. 1928. (Demy 8vo pp x + 362. 11s 6d net.)
³ *Childbirth*. By William George Lee. A.B. MD Chicago. The University of Chicago Press. London: Cambridge University Press. 1928. (Roy 8vo, pp xi + 230. 15s net.)

to far to outstrip the art. In his own words, the mass of detail in the heavy tomes written from a narrow technical standpoint has put the student in the place of Yankee-Doodle who "couldn't see the town, there were so many houses." He thinks the teachers of obstetrics are to blame for keeping new wine in old bottles and could put the time allotted to them in the curriculum to more advantage by greater concentration on principles and practice.

The care of the pregnant and lying-in woman is regarded as consisting largely of an application of the principles acquired in the study of general medicine and surgery, whereas in parturition special knowledge and training are required because of the rapidly succeeding and striking changes that occur then and which may endanger the life of mother and babe. It is here that the general practitioner is prone to deviate from the high plane of his art. His judgement and skill are not apt to work swiftly, for the restriction upon his time prevents the constant observation necessary for proper obstetrical care. During the period of short and rapid change "many women suffer, either from failure to recognize in time progressively increasing peril or from subjection to a needlessly early operative attack." The need for continued and careful observation throughout the whole course of labour is stressed, and full instructions are given as to accurate record keeping. The chapters on the forceps and its use will be found of particular interest. The agitation for an undue limitation of the forceps and the search for inferior methods of delivery the author considers to be due to a lack of knowledge of the mechanical principles involved, and he therefore devotes much space to a consideration of these principles and how they are applied in specific conditions.

The book is beautifully turned out and a pleasure to read. Its paper, type, and wide margin do credit to the Chicago University Press. It may be prescribed with confidence as an antidote to the heavy tomes that drove the author into other paths, and will repay study by those interested in obstetric problems.

EXPOSURE OF LONG BONES

In the pre-anæsthetic days, when surgical procedures were comparatively few and well defined, each step in an operation was clearly described and taught to the student in the practice of operations on the dead body. The immense extension of the field of operative surgery since the introduction of anaesthetics and asepsis has led perhaps to some neglect of exact teaching of this subject, in view of the multiplication of procedures and the magnitude of the task of teaching all of them. Professor ARNOLD K. HENRY's book will be welcomed as supplying a want in this connexion as well as introducing some novel operative measures and appliances. In *Exposure of the Long Bones and other Surgical Methods* he describes ways of gaining access to the shafts of long bones with the least damage to the soft parts, and with the fullest possible exposure of the field of operation. For instance, the usual lateral incision for plating the shaft of the femur necessitates much division of muscular tissue and takes little heed of the presence of important blood vessels, while it is awkwardly situated unless the patient is laid on his side. Professor Henry's methods minimize all these drawbacks, and their adoption should increase the security of patients from the risk of hæmorrhage. In the second part of the book are described original methods of approach to the cervico-dorsal ganglia of the sympathetic in Jönnesco's operation for angina, and to the vertebral and subclavian arteries from behind, and also an original apparatus for the practice of pituitary surgery by a new method. The author's cup-and-ball aneurysm needle for deep ligations appears to us to be an ingenious and practical appliance of considerable value. As Sir WILLIAM WHEELER says in a foreword "Professor Henry's book not only is full of good things, but overflows with practical information which cannot be obtained from any other source." The illustrations render the descriptions effective beyond any doubt.

Exposure of the Long Bones and other Surgical Methods. By Arnold K. Henry, M.D., N.C.H. Univ. Dublin. Foreword by Sir W. I. de C. Wheeler, Bristol. J. Wright and Sons, Ltd. London. Simpkin Marshall Ltd. (M.D. 8vo pp. xii + 80, 51 figures, 10s. 6d. net.)

PHYSIOLOGY

PHYSIOLOGY must, on the whole, be accounted fortunate in the excellence of her teachers. Prominent among these must rank Professor WILLIAM H. HOWELL, whose *Text-Book of Physiology*, which now appears in a tenth edition,¹ has won for him a great body of students vastly out-numbering those who have been privileged to attend his classes at Johns Hopkins University. In these days, when the bulk output of the research laboratories of the world continues to increase on a curve which gives no indication of a slackening rate, and when the literature of science becomes more and more highly specialized, the value of the "old fashioned" comprehensive textbook should, and we believe does, become more fully appreciated, it is indispensable. At the same time the labours of its author are correspondingly increased, so that, indeed, it is now well-nigh beyond human powers to be familiar at first hand with all the original literature which deserves a place in such a book. Professor Howell acknowledges that he has only been constrained to revise once more his book by the appreciation of "a certain obligation, in the case of a book already established, to maintain its usefulness as far as possible by the preparation of new editions at frequent intervals." It is our obligation to acknowledge with gratitude the magnitude of the labour involved. In the case of this latest edition our thanks are unqualified, since it indicates a very patient, enlightened, and judicious revision of the text. The chapter headings remain unchanged, the new matter being skilfully woven into the text so that the fabric bears no patent signs of renovation. That new cloth can be sewn into an old garment is a pretty compliment to the garment.

Under the title of problems of the moment in physiology² Professor LÉON BINET publishes the substance of a series of "conférences" held by the Faculty of Medicine of Paris during the academic year 1925-26. So much is indicated by the preface, but it is difficult to comprehend the precise character of these "conférences." Twenty-four chapters deal with twenty-four more or less distinct problems, fourteen of these occupy less than ten pages, and in the form in which they are here presented they could have occupied an audience only a few minutes. It will be clear, therefore, that they make no serious attempt to survey the present state of the physiological problems with which they are concerned. Indeed, the majority of the chapters represent brief summaries of a variety of researches upon which members of the faculty have recently been engaged. Much of it has been published already in the scientific journals in more adequate detail, and actually some of the lectures have already appeared in *La Presse Médicale*. The book scarcely justifies its attractive title, and appears to serve no useful purpose other than to survey the recent activities of this prominent French school of physiology. The problems to which the various chapters are devoted are too numerous and unconnected to allow brief review. They range from histological studies of the lungs, various respiratory and excretory questions, digestive functions of the pancreas, to thirst, sleep, and tobacco smoke.

APPLIED CHEMISTRY

THORPE's *Dictionary of Applied Chemistry*³ seems to touch upon every subject to which chemistry has been applied. It may fairly be said that there is hardly anything comprised in the term chemistry that is not effectively described and explained in its pages. One of the most remarkable articles is that on water, it treats of the chemical purification of water, indicating the subtle nature of the impurities which are most difficult to detect and remove in preparing water of absolute purity, it gives the physical properties and constants connecting pressure with freezing and boiling points, and describes varieties of ice.

¹ *A Text-Book of Physiology.* By William H. Howell, Ph.D., Sc.D., LL.D. Tenth edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company. (Med. 8vo pp. 1681, 308 figures, 50s. net.)
² *Questions Physiologiques d'Actualité.* Par Léon Binet, Paris. Masson et Cie. (6½ x 9 pp. 221, 65 figures, 18 fr. sans majoration.)
³ *A Dictionary of Applied Chemistry.* By Sir Edward Thorpe, O.B., LL.D., F.R.S., assisted by eminent contributors. Vol. vii revised and enlarged edition. London and New York: Longmans, Green and Co., Ltd. 1927. (Med. 8vo, pp. viii + 763, 60s. net.)

which are heavier than water. All these matters are discussed with a wealth of detail, much of which is of absorbing interest, such, for example, as the fact that but for the compressibility of water, slight as it is, the mean sea level would be 116 feet higher than it now is, and about 4 per cent of existing land would be submerged. Viscosity, surface tension, refractive index, magnetic and electrical properties, are a few of the many items relating to water on which detailed information is given. One section treats of the constituents of natural spring waters, another of potable waters and the various forms of pollution, their causes and the means by which they may be detected. The article on water is typical of the whole character of the dictionary. All the different aspects of every chemical subject are adequately noticed, and the interest is not restricted to any particular section or group. Pure chemistry, inventions, medicines, and the arts are all represented, and what is lacking in the text of the work is made accessible by the copious references to original publications. The seventh volume, now published, makes the new edition complete. It is an invaluable work to those whose occupation is concerned in any way with applied chemistry.

NOTES ON BOOKS

Diabetes, its Treatment by Insulin and Diet,* is a handbook prepared for the instruction of diabetic patients by Dr O. H. PERRY, who is professor of diseases of metabolism in the University of Pennsylvania. The purpose of the book is to provide the patient with the information necessary to enable him to make an intelligent choice of diet. The author emphasizes the point that this volume is in no way intended to act as a substitute for medical advice, but merely aims at providing the information essential for the intelligent carrying out of medical instructions. Its success is indicated by the fact that it has passed through four editions since its appearance in 1924. The present edition has been somewhat enlarged and certain sections have been rewritten. Perusal of the work shows that care has been taken to bring it completely up to date.

We have received a copy of Professor RICARDO JANCE's work on alastrim and post-vaccinal encephalitis,† which first appeared in the *Archivos do Instituto Central de Higiene*. The work is divided into two main parts. The first, which deals with the relation of alastrim to small pox, contains Professor Jorge's address on this subject delivered before a meeting of the International Office of Public Health in Paris in October, 1924, followed by a slightly abridged translation which appeared in the *Lancet* of December 20th and 27th, the correspondence in subsequent numbers of that journal and the discussion which ensued at the meeting in Paris. The second part deals with the occurrence of encephalitis following vaccination in Holland, Great Britain and Switzerland, and contains two papers presented respectively to the International Office of Public Health in October, 1925, and a special conference convened at the hospital under the auspices of the League of Nations in January, 1926. Epidemiologists will be glad to have collected in book form these important papers by a leading authority, though it is obvious that in neither of the subjects discussed has finality been reached.

How to Drive a Car,‡ by the editor of *The Motor* and his staff, suffers from the effort to make the book fool proof. Hence much vain repetition and a multiplicity of words, wherein the would-be motorist may become befogged. Many of the dangers and emergencies of driving are depicted in illustrations, but for acquiring the art of skidding round corners the reader is left to letterpress which is not a model of lucidity. Early in the book it is stated that a driver must possess not only a licence, but also a knowledge—by heart—of the rules of the road, most of which would be pointed out in a later chapter. We have been unable to find this chapter, perhaps because when the editor got to it, he discovered that no proper index existed.

* *Diabetes, its Treatment by Insulin and Diet*. By Orlando H. Perry, M.D., F.A.C.P. Fourth revised and enlarged edition. With an introductory foreword by John D. Deaver, M.D. Philadelphia: F. A. Davis Company, 1928. (51 x 74 pp. 152 figures. 2 dollars net.)

† *Alastrim et Varicelle—Encephalites post-vaccinales*. By Ricardo Jorge. Lisbon: Instituto Central de Higiene, 1927. (Sup. 8vo. 80 pp. 1r + 183.)

‡ *How to Drive a Car*. By the Editor of *The Motor*. Tenth edition completely revised. London: Temple Press, Ltd., 1928. (Cr. 8vo. pp. 311 + 144 illustrations. 2s. 6d. net.)

INTERNATIONAL CONFERENCE ON CANCER.

MEETING OF DELEGATES IN LONDON

THE International Conference on Cancer, arranged by the British Empire Cancer Campaign, has been held in London this week. Delegates attending from abroad numbered just over one hundred, representing fourteen European countries, the United States, China and Japan, and six British Dominions, in addition, more than two hundred representatives of British hospitals, medical societies, public departments, and branch sections of the Cancer Campaign were registered. The British Medical Association was represented by Mr R. G. Hogarth, Past-President, and Sir Thomas Horden.

Reception by the King

On the day of assembling (Monday, July 16th) the delegates, from abroad, together with the officers and members of the Grand Council of the Empire Campaign, were received by the King at Buckingham Palace. In reply to an address presented by Sir John Bland-Sutton, President of the Conference, His Majesty said:

I thank you very sincerely for your address and I am happy to welcome the delegates of the International Conference on Cancer. It is both gratifying and encouraging that representatives of universities, medical schools and other learned bodies and men who have won distinction in all parts of the world by their work in research medicine and surgery, have been able to attend this Conference. We in this country are indebted to the British Empire Cancer Campaign for much useful service in the field of cancer research and particularly for organizing this Conference to take counsel together for the relief of suffering humanity. This large and distinguished assembly is a happy omen for the final success of the campaign for they will have opportunity of looking from every angle at this great and complex problem of contributing to the general knowledge any light upon the subject gained by individual experience and of discussing and comparing the various practical methods for combating the disease. In struggling against so powerful and insidious an enemy there is need for the most efficient staff work and the closest co-operation between all arms of our forces.

I note with interest that your object is research both into the cure and causes of cancer. No doubt in the last resort the discovery of the cause is the only certain and absolute means of cure. But I am glad that you have not ignored the practical side of the problem. Remembering the thousands of sufferers from cancer I feel that if your discussions lead to advance in diagnosis, treatment or even palliation of the disease, this Conference will have justified itself and earned the gratitude of mankind.

I am grateful for the assurance that you recognize my sympathy shared also by the members of my family with the work upon which you are engaged. Throughout his life my father was deeply interested in all hospital work and especially in cancer research, and I myself as President for several years of the Cancer Research Association know the value of their labours and am glad that my second son is now President of the British Empire Cancer Campaign.

I appreciate your pledge to pursue your quest to the end and wish you God-speed in your arduous and beneficent work, trusting that in years to come men may be able to look back to the deliberations of this International Conference as the beginning of ultimate triumph in the long war against cancer.

In the evening a reception to the delegates and their ladies was given by Sir John and Lady Bland-Sutton at their house in Brook Street.

Opening of the Conference

The delegates met on Tuesday morning at the house of the Royal Society of Medicine when a letter of welcome was read from the Duke of York, who expressed the hope that the united experiences of those attending the Conference would mean that a stimulus was given to the hospitals, institutions and research centres from which they came, and to which they would return refreshed with new ideas and more intimate knowledge. He added that although he and the Duchess of York would entertain the delegates at Lancaster House, St James's, on the following evening, he could not let the opening of the Conference pass without wishing God-speed to all concerned.

SIR JOHN BLAND-SUTTON contented himself with the briefest of opening addresses. It was recognized by wise men who studied nature closely, he said, that living matter manifested an innate rhythm which induced insects to swarm and vertebrates to congregate, this irresistible impulse was for the welfare of the species, and was

manifest also in human beings "We are to-day in the midst of a swarm of able men keenly interested in a disease which, if we may believe the alarmist reports of irresponsible writers in the lay papers, threatens to exterminate civilized human beings. In this hive of busy men we have physicians, surgeons, pathologists, bacteriologists, radiologists, physicists, and statisticians—indeed, as much subdivision of labour as may be found in a hive, a foramen in a, or a terminus. Out of this world-wide swarming we hope much good may come to allay public anxiety in regard to this puzzling disease. The profession is neither torpid nor asleep in regard to the importance of grappling with the problem, and I offer in the name of the British Empire Cancer Campaign a hearty welcome to all delegates, many of whom have travelled long distances over sea and land to help in devising means for the conquest of cancer."

After these opening proceedings the delegates divided themselves into two sections, some remaining at the Royal Society of Medicine for a discussion on "The relative values of surgery and radiation in the treatment of cancer of the cervix uteri, rectum, breast, and buccal cavity," which was arranged to occupy two mornings, while other delegates went to the College of Nursing, where a discussion was held on "The etiology of cancer."

RELATIVE VALUES OF SURGERY AND RADIATION

In the first discussion, which was presided over by Sir JOHN BLAND-SUTTON, the general subject was opened by Professor C. REGAUD, of the Radium Institute, Paris. The radio-sensitivity of cancers, he said, was extremely variable. In Paris the term "epidermoid epithelioma" had been used to describe a stratified pavement epithelioma, which structurally exhibited in some degree the morphological changes or manner of growth peculiar to the epidermis. Such epidermoid epitheliomata of the skin, mouth, cervix uteri, and vagina formed a homogeneous pathological group and displayed a similar behaviour towards radiation. Of the two different species of cancer, epidermoid and glandular, in the same situation—the cervix uteri—cures by selective radiotherapy had been obtained only in the former. The cause of this difference of behaviour appeared to depend on the activity and rhythm of division on the one side and the secretory function on the other. In addition, many other factors independent of radio-sensitivity influenced the results of radiotherapy, such as the extent of the primary cancer, its distant spread, its accessibility to the various radiotherapeutic procedures, and the variable robustness or radio-resistance of the tissues and organs through which the rays had to travel before acting on the tumour. Ray action could be brought to bear on a small neoplasm which was out of the question in one more extensive. His conclusion was that none of the methods of treating cancer could promise uniform success, the judgement must remain impartial, and the various fields of technique continually compared.

Cancer of the Cervix Uteri

Dr MALCOLM DONALDSON (St Bartholomew's Hospital) gave the following grounds for definitely deciding in favour of radiation as against hysterectomy:

- (1) The negligible mortality due to the radiation treatment.
- (2) The fact that statistics of survival rate are in no way inferior in the case of radiation to those following hysterectomy.
- (3) By improving the technique of radiation treatment the number of patients who seek advice early will be increased and the results will correspondingly improve.
- (4) It will bring into general use radiation treatment for those cases which have passed the possibility of being completely restored to health.
- (5) It will encourage the younger generation of gynaecologists to adopt a method of treatment which the greater number will be able to carry out more successfully than Wertheim's operation, recognized as one of the most difficult operations in the whole domain of surgery.

Dr Donaldson suggested that an international bureau of medical statistics should be set up by the League of Nations

whereby certain standards might be recognized with which surgeons would have to comply if they desired universal acceptance for their figures, also that much might be done for the education of the public if insurance companies would give special terms for those who presented themselves every six months for medical examination. Dr A. LACASSAGNE (Paris) held that correct treatment in every case must comprise irradiation by multiple foci. Four very variable factors conditioned the success of radiotherapy—namely, the extent of the disease, the quality of the treatment, the histological variety of the tumours, and any associated infection. Dr W. P. HEALY (Memorial Hospital, New York) said that epidermoid carcinoma of the cervix might be classified histologically into three grades, based primarily upon the degree of anaplasia. These groups corresponded with three degrees of potential malignancy, as well as with three grades of radio-sensitivity (low, medium, and high). The factors which determined prognosis in carcinoma of the cervix, as in other diseases, were multiple, the most important were the clinical stage of the disease at which treatment was instituted and the radio-sensitivity of the tumour. When surgery was employed the important factors in prognosis were early diagnosis and the degree of malignancy as indicated by the cell type in the individual tumour. He believed that the treatment of carcinoma of the cervix by radium and x-rays offered better results than surgery, without the attending operative mortality. Dr MAX CHEVAL (Brussels) described how, for two years, he had used a device containing 4 grams of radium element to treat deep-seated tumours by means of large fields, as usually practised in x-ray therapy, and he reported continuing good results. Just as better results had been obtained in surgery by extended operations as against the old-fashioned technique of parsimonious excisions, so, he believed, in radiotherapy the same thing would occur. Dr ZWEIGEL (Munich) compared the results of various workers—mostly German—in treating cancer of the uterus by radiation and by surgery. The percentage results of the two methods worked out to about the same.

The discussion of this part of the subject was concluded by two British surgeons. Mr COMPTON BERKELEY gave figures relating to his experience of radical operation for cancer of the uterus. He had analysed the notes of more than 600 cases operated on by himself and Mr Victor Bounce, and going back to before the radiation era. The immediate mortality was 17 per cent, but he pointed out that such mortality was largely a matter of fortune, he had operated on two series of 36 and 22 cases without a death, followed by 9 deaths in 18 cases. It was his custom to remove all glands, large or small. In 616 cases, 276 had carcinomatous glands, and 340 had not. From a study of figures at his disposal, if the glands were carcinomatous the immediate operative mortality was raised from about 12 to 20.6 per cent. Of 240 patients alive at the end of three years, out of a total of 517, 36 per cent had had carcinomatous glands, and out of 162 alive at the end of five years, 37.8 per cent had had such glands. Mr Victor Bounce remarked that he was not there to defend surgery as against radiation. He had always said that when radiologists proved by figures that they got better results than surgery, he would abandon surgery and take to radiation. But it was a question of classification. Instead of splitting up figures into a dozen categories it would be better for the radiologist simply to present the sum total of the cases he had treated by radiation and those that had survived five years. For himself he thought five years not enough, ten years should be taken before absolute cures were claimed. With regard to his own figures, up to the end of 1926 he had operated on 332 cases and had had 52 deaths—an operative mortality of 15.9 per cent. There were 137 deaths by recurrences, and of the remaining 143, 13 died of other diseases, but 6 of them after the five-year period had passed, 30 had been lost sight of, but 17 of these had been under observation for at least five years and 100 of the total number were still known to him, and of these 64 had passed the five-year period. Further, 51 patients were alive and well from ten to nineteen years after operation, out of this total of 332.

Cancer of the Rectum

Sir CHARLES GORDON WATSON, opening this part of the subject, said that his experience of the use of radium for cancer of the rectum by open operation dated only from a visit to Dr. Neuman's clinic in 1925. Since then he had himself treated 27 cases of cancer of the rectum, employing radium salt in platinum needles. He described in detail his methods of approach by open operation from the perineum and by direct barrage through the abdomen, with radium barrage per vaginam and radium in bulk in the lumen of the rectum. In his opinion the whole future of successful radiation of cancer tissue would depend upon the possibility of administering an optimum dose in any individual case at the present time empiricism was the main guide, and standards must necessarily be rough. Of the first 15 of the 27 cases, 2 were taken to be cures, and of the more recent cases there were several which he hoped would be cured. With one exception, all the cases had shown a period of improvement. The time might come when there would be such control of the action of radium that it would be possible to say that a case, though suitable for a radical surgical operation, could be cured with greater certainty and less risk with radium.

Mr. W. FINEST MILES, with the aid of some excellent schematic illustrations, described the method of cancer spread from the primary growth in the rectal wall to the parts outside the rectum. He showed that the dissemination of cancer cells by what he called the extramural lymphatic system was more widespread and of much greater consequence than that which involved the intramural lymphatics, and that of the three zones of possible extramural spread the upper zone was the most important. Since 1907 he had consistently employed the abdomino-perineal operation in all suitable cases, planning it so that the tissues comprising the upward as well as the downward and lateral zones of spread could be widely removed. The survival rate was infinitely better than in the case of the operation performed from the perineum alone. Mr. J. P. LOCKHART-MUNTER gave particulars of 223 patients who had survived operation for cancer of the rectum, of whom 130 were operated on more than five years ago. When operation was performed under most favourable conditions the mortality was about 35 per cent, and the cures on a five-year basis 50 per cent. He thought it could be said that the best method of treatment for cancer of the rectum was by operation, that the prospects of cure were good, and in early cases excellent, and that no facts had as yet been brought forward to justify the recommendation of radiation treatment in place of operation where the latter was possible. The final contribution of the morning was that of Dr. DOUGLAS QUICK (New York), who spoke of radiation methods, preferably radium, in inoperable cases.

THE ETIOLOGY OF CANCER

The second discussion was presided over by Lord DAWSON of PENN, who said that medicine, above all other callings in the world, was a cementing force between the nations. Physicians and surgeons were gathered during this week as comrades to try, by the exchange of ideas, to do something towards removing one of the great scourges of the world. In a problem of such magnitude there were many and great difficulties, and so those attending the meetings did not come in any spirit of light-hearted optimism, thinking that by the exchange of a few words the gigantic problem would be removed, all that could be hoped was that this conference might do something to promote a further stage in its elucidation. Only by a summation of the results of the efforts of workers of all nations could real advance be made, only by treading the narrow road of patience and perseverance would victory eventually come.

Professor JAMES EWING (New York) opening the discussion, said the problem of the origin of tumours was different from that of their continued growth. Therefore one question concerned the exciting factors the other the nature of the tumour process itself. The exciting factors of cancer did not act alone, but always with predisposing causes. The most important and oldest conception of the origin of cancer was that of chronic irritation, and the supervention of cancer in previously normal cells through

a series of complex tissue changes, had been experimentally proved. Some irritants excited only a slowly progressive process, so that it was a long time before the stage of actual cancer was reached, as in the case of leucoplakia following excessive smoking. Soft x rays and to a less extent sunlight and heat produced cancer, and carcinoma had been known to develop after a single burn of the skin. Cancer of the penis, unknown in Jews, could result from the irritation of decomposing smegma and infection. The older physicians were probably correct when they said that cancer of the mouth would probably disappear if tobacco, bad teeth, and syphilis could be eliminated. A fruitful field of research lay in the analysis of the factors of irritation surrounding the inception of such acinar structure as the pancreas, liver, salivary glands, prostate, and thyroid. The question of trauma as a producer of cancer was still a highly controversial one, but the doctrine of precancerous lesions was an essential part of the irritation theory. It seemed clear that cancer arose only on tissue which had become altered by chronic irritation.

Referring to heredity, Professor EWING said generalizations on this matter were unsafe, each form of cancer must be regarded as a problem by itself. No satisfactory evidence was forthcoming of a hereditary predisposition to cancer in normal tissues. Miss SLYE of Chicago had clearly shown that selective breeding in mice might intensify the hereditary tendency. So far there was no complete answer to the query as to how the cells acquired the property of absorbing nutriment and multiplying incessantly to the great detriment of the body. The most profitable field of research dealt with the presence of growth-stimulating substances in embryonic and tumour tissue. Warburg, in his researches on the tissue respiratory rates and the lactic acid content, had contributed a valuable chapter on this subject. Professor EWING declared that there was no one exciting cause of cancer, nor one great secret in the cancer cell.

Professor F. BLUMENTHAL (Hamburg) pointed out that not all cancers arose from a parasitic origin, and said that cancer belonged to the category of malignant blastomas. All cancer stimuli seemed to be exerted by way of an inflammatory stage.

Professor ARTHUR LEITCH (London Cancer Hospital) said that in the last twenty years two outstanding discoveries had intrigued the minds of experimental pathologists, the first of which was due to Rous and Murphy and the other to the late Johannes Fibiger. The latter was the first to produce cancer experimentally. It seemed now necessary to modify considerably the theory of irritation in respect of cancer as originally stated, since only a few irritating substances seemed able to induce tumour formation. For example, a pyrogenous extract of tobacco was applied to the skin of mice for a long period, and though chronic ulcerations resulted, at no time did neoplastic growth occur. Moreover, what would produce cancer in one species of animal would not do so in animals of a different species. All carcinogenic agents acted slowly, the fact that cancer was a disease of middle or old age could not be attributed to mere senility of tissues, it was those who had reached that period of life had allowed the necessarily long time to elapse. Even when it was clear that some biological change had occurred the cell was anatomically normal. He discussed the claims of Gie and Barnard to have discovered a cancer virus from fowl tumour, which he negatived. He thought that the "growth substance" might yet come within the range of experimental investigation.

Professor A. BONNEL (Strasbourg) showed a large series of slides illustrating his investigation of the rat liver sarcoma, and the adeno-carcinoma of the mouse. The cancer age, he pointed out, coincided with the age of whitening of the hair, at which time the trophic system became a phagocytic system.

Professor H. T. DEELMAN (Groningen) discussed the question of leucoplakia and its relation to cancer in a woman aged 72, who had a small cancer on the mucosa of the mouth, but it was not ulcerating. Microscopically the tumour tissue passed gradually into the surrounding leucoplakia, there was no sharp boundary between the two. There seemed to have occurred a gradual change of the

pre-existing epithelium into cancer cells in a centrifugal direction. In the very early stages of the growth there were appearances only explicable on the assumption of inductive growth.

Dr J B MURPHY (New York) said that now, after many experiments of a crucial character, the real nature of the cancer agent seemed to be emerging. Two striking facts seemed, he thought, to indicate that one had to deal with endogenous chemical substances rather than with extrinsic living viruses. The first of these was the selectivity of the tumour agents. His chicken tumour No. 1 at first would grow, for four generations, only in blood-related animals of a special strain of Plymouth Rocks, for another eight generations it grew only in another pure-bred Plymouth Rock strain. Only after many generations would it grow in any other variety. The second point concerned the specificity of the types produced. The parasitic theory of cancer formation he regarded as highly improbable, from several considerations which he enumerated.

Professor J MURIN (Louvain) dealt with the question of metabolism and experimental cancer, and related the research he had conducted with the electrolyte ionium. This disintegrated slowly, giving off only alpha rays. Injected in large doses before commencing tar applications, and in moderate doses during them, it resulted in a reduction of the time needed for the induction of cancer in mice, and in tar cancer in rabbits it prevented the regression of the cancers after tar applications had been discontinued. He was still working on the influence of various albuminoid substances on tar cancer, and had tried the effects of various diets in this form of cancer. So far the effect of the liver diet of Whipple and Minot was seen to be to accelerate the evolution of tar cancer, and an effort was being made to determine the nature of the active substance.

Professor RHOEA LOEWY spoke of her attempts to produce cancer in animals by giving them diets which were over-rich in certain constituents, such as vitamins B and D. In giving such foods it was found that the respiration quotient was altered—namely, from the average of -0 to -4 . It was clear from her work, she said, that cancer was not a local disease, but a change in the whole body metabolism, a change which could be brought about by a variety of means.

Professor J MCINTOSH (London) said that the various theories which had been put forward in explanation of the development of cancer could be collected under two groups: biological and parasitic. He dealt shortly only with the virus theory. If a virus was so small that it could live and multiply in the interior of cells it was well situated for influencing such cells. Hitherto, he thought, the virus theory had been regarded too lightly, as the evidence had not been well balanced. The evidence that the Rous sarcoma was due to a filterable virus the speaker regarded as good, though, so far, there had been no experimental evidence that ordinary mammalian tumours contained a virus. Attempts to cultivate the activating agent had been inconclusive.

Dr TEUTSCHLAENDER (Heidelberg) said that three important factors had to be understood in attempts to prevent cancer—that is, (1) the exogenous agent in relation to the cells capable of growth, (2) the disposition (local and general) of the organism concerned, (3) the exposition. All three must be present, though their relative degree might vary. In the case of endogenous cancers, irritation played a secondary role in comparison with that in irritation cancers. He dealt at length with the question of the long exposure of healthy cells to cancerogenic agents as a necessary preliminary to the onset of true cancer.

Professor BIERICH (Hamburg) referred to the accumulation of lactic acid in cancer tissue, all cancer tissue was rich in this acid, and it proceeded to invade neighbouring tissues, so breaking down barriers which might otherwise have hindered the progress of the disease.

Professor PROUST (Paris) concentrated on cancer of the skin, and suggested that public authorities in all countries should closely watch the cultivation and handling of vegetables eaten by the people.

MEDICINE AND DIAGNOSIS

On Wednesday morning the conference met in four sections—Medicine and Diagnosis, Surgery, Radiology, and Pathology and Public Health. In the first section, over which Sir WILLIAM WILCOX presided, a discussion took place on "Some present-day medical aspects of cancer."

Cancer Cachexia

Sir THOMAS HONNER pleaded for a policy of more activity in very many cases of cancer cachexia. Too often one saw a meagreness of effort to combat the condition which betokened the doctor's hopelessness. Even when the growth was inoperable the treatment of the cachexia must be faced, and the attitude of the medical man should be to prolong life by all means in his power without adding to the patient's discomforts. The treatment of the general health in cancer was important as an adjunct to whatever was being done for removal or resorption of growth. The intrusion of the hyman with his pancreas was a tiresome obstruction, and the gratuitous advertisement given him by certain of the medical profession was an almost intolerable nuisance. In the matter of diet a wave of enthusiasm was now being witnessed in favour of vegetables and fruit, but the testing of diets at the Cancer Hospital led to the conclusion that patients suffering from inoperable cancer maintained their weight, general tone, and morale much better on a mixed diet than on the type of dietary just mentioned. Of the relief of cachexia after radiation treatment in some inoperable cases there could be no doubt. The keen practitioner would watch his patient carefully for the possibility of helping him by means of limited operations, if he could not control sepsis by this means he might do so by diathermy, by light, or by the use of antiseptics. Antigen therapy was sometimes of definite assistance in this connection.

Dr WILLIAM HUNTER remarked that cancer cachexia now was not comparable with what it was thirty or forty years ago, when a truly ghastly picture was presented.

Primary Carcinoma of the Lung

Dr ROBERT HUTCHISON (London Hospital) opened a discussion on the alleged increased frequency of primary carcinoma of the lung. He gave figures from his hospital records from 1907 to 1925, which suggested that there had been a steady increase in such cases during the last decade—not only an absolute increase, but a relative increase to carcinoma in general. His study of the records did not lend much support to the idea that the increase was to be attributed to the great epidemic of influenza. Nor was there any clear evidence in favour of the theory that the cause was irritation of the lungs by dust and fumes, though it was certainly suggestive.

Dr L S T BURRELL (London) spoke of each of the three groups in which malignant disease of the intrathoracic viscera was seen by the physician—namely, endothelioma of pleura, carcinoma of lung, and sarcoma of mediastinum—and indicated some possibilities which should not be forgotten in the diagnosis of intrathoracic neoplasms. Dr POWELL WHITE (with Professor Shaw Dunn) brought forward the results of an inquiry made by the Manchester Committee on Cancer into the incidence of primary intrathoracic cancers at various large hospitals in Great Britain. A clear and steady rise in the percentage of these cases as revealed at autopsies was shown. Of the six large cities taken, Manchester showed the highest percentages and the most consistent increase. Professor T SHENNAN (Aberdeen) described, with the help of some beautiful photomicrographs, twenty-two tumours of the bronchus and lung removed *post mortem* from adults. He mentioned that a factor possibly of very considerable etiological importance was the presence of old standing pulmonary disease. Professor W G BARNARD (London) described certain growths frequently called "out-celled" tumours, which had in the past, with few exceptions, been regarded as sarcomata of the mediastinum, and showed that they were in reality medullary carcinomata.

In the course of more general discussion Dr LEONARD HILL gave an account of some feeding experiments on

mico. Large numbers of the animals developed papillomata of the lung, especially as age advanced—that is, in the second year—but the quality or the adequacy of the diet appeared to have nothing to do with the incidence. Professor DUNCAN GRAHAM (Toronto) testified that in his city a definite increase in primary cancer of the lung had been noted during the last ten years. He had no suggestion to offer as to the cause. Dr J G TULL said that in Singapore no increase in primary cancer of the lung was observed, but secondary infections of the lung were seen following the widespread frequency of primary cancer of the liver. Dr JOHN ANDERSON (Hong Kong) said that among 5,000 autopsies he had only seen primary carcinoma of the lung in one case. Dr A T TONN (Bristol) mentioned the possibility of arsenic as a cause of cancer, in view of the widespread use of arsenic in treating syphilis. Dr W C MACCARTY (Mayo Clinic) also had experienced an increase in primary carcinoma of the lung. Sir WILLIAM WILCOX said that at St Mary's carcinoma of the lung certainly appeared to be much more frequent than formerly.

SURGERY

Bone Sarcoma

The Section of Surgery met, under the chairmanship of Sir CHARLES GORNO-WATSON, to consider the classification and treatment of bone sarcoma. The discussion was opened by Professor JAMES EWING (New York), who presented a classification of bone sarcoma into osteogenic, giant-cell tumours, myeloma, and liposarcoma, with subdivisions of the first three. He supported his classification by the presentation of typical cases, and then proceeded to demolish it by the presentation of atypical cases which apparently did not come into the categories cited. Nevertheless, Professor Ewing thought that certain exceptions and intermediates did not destroy the value of the classification. With regard to methods of treatment, he considered that osteogenic sarcoma of the periosteal, medullary, and subperiosteal, telangiectatic, and sclerosing types were best treated by immediate amputation. It would, however, be possible to obtain a certain proportion of successful results in periosteal sarcoma by radiation, and this applied also to fibrosarcoma. Giant-cell tumours, with certain exceptions, were best treated by radiation. He did not think there would be any great improvement in therapeutic results in the group of bone sarcomas so long as those concerned followed the plan of waiting for the full development of the disease so that it could be recognized in the radiograph or by clinical observation. The time had arrived when surgeons and pathologists should recognize that osteogenic sarcoma should be treated on suspicion.

Mr SAMUELSON HANDELY said that for periosteal sarcoma of the long bones he had adopted radium treatment of the tumour, using heavy doses, the technique of which he described to the Section. He was able to point to quite a small group of cases in which that treatment, repeated once or more, had been successful over periods of time up to nine years. In the radium treatment of periosteal sarcoma it was necessary to ignore the danger of producing a limited necrosis of the normal bone in the neighbourhood of the tumour. Unless that risk was taken it was probable that the dose given would be insufficient to destroy the tumour. He confessed that such a method of deliberate risk was far from ideal, but he anticipated that with improved technique it would be possible to avoid the danger. Dr W B COLEY (Cornell University) described his toxin method of treatment of malignant bone tumour by selective poison, many of his patients remained well from eight to eleven years after treatment. Mr R C EASLIE thought curretting a more hopeful procedure in endosteal tumours than was generally realized. In diagnosing endosteal tumour only one method was safe—namely, exploration and careful microscopic examination. Even then it was necessary to remember that the cellular structure of endosteal tumours varied so enormously that mistakes arising from hurried microscopic examination were not uncommon. Professor M J STEWART (Leeds) spoke on giant-cell tumour and myeloma of bone, and the discussion was continued by Mr JULIAN TAYLOR (University College Hospital) and Dr

CHANNING SIMMONS (Harvard), the latter describing the results of amputation in cases of giant-cell and other tumours. Professor FICHERA (Italy) spoke of the necessity in diagnosis of recognizing atypical conditions.

In the Section of Radiology a discussion took place on biological effects of radium and x rays, and in the Section of Pathology, Statistics, and Public Health the subject of occupational cancer was debated by many speakers. Reports of these discussions will appear in our next issue.

MIDDLESEX HOSPITAL BANQUET

On Tuesday evening the Board of the Middlesex Hospital and the Middlesex Cancer Hospital and the Council of the Medical School and Bland-Sutton Institute of Pathology entertained a large company to dinner at the Savoy Hotel. Prince Arthur of Connaught, Chairman of the Hospital, presided.

The main toast, that of 'Cancer Research', was proposed by Mr ERIC PEARCE GOULD, Dean of the Medical School, who welcomed the distinguished workers in all branches of the field of cancer research now gathered in London. He said that the Middlesex Hospital was proud to think that so far as the special study of this disease in recent times was concerned it had been early in the field. The charity of Samuel Whitbread (1720-1796), whose portrait appeared on the dinner programme, gave to the Middlesex Hospital its first ward set apart for cases of incurable cancer. The first notable work on cancer was published by members of the hospital staff in 1857. He believed that any success that had attended cancer research since those days at the Middlesex Hospital was due in no small measure to the fact that the work had been carried out in an institution which combined under one management a general hospital with a complete medical staff, a medical school with teachers of distinction, and complete departments for all its branches, and special personnel and laboratories for research. From this combination arose the possibility of co-ordinating cancer research in all its branches—clinical, pathological, biological, radiological, and statistical. In the belief that there were special opportunities for doing valuable work at hospitals where the clinical and experimental aspects could be studied side by side, they recognized with peculiar satisfaction that the British Empire Cancer Campaign—to which they owed the conference that occasioned the dinner—had seen fit to support in the most handsome way the progress made before the Campaign was founded, at the Middlesex Hospital and the Cancer Hospital, and, further, that the Campaign had made possible the institution of cancer investigation work at many other important London and provincial hospitals. The lay public were perhaps impatient that the lavish expenditure of effort of which it read, and the money it was asked to provide, had as yet apparently resulted in so little. Workers on the problem of cancer did not share that impatience, believing two things—that Nature revealed her secrets only to the importunities of patient, unwearying, honest endeavour, and that in the case of cancer research the goal at which they aimed was worth generations of this toil. In conclusion Mr Pearce Gould asked the company to drink with him in silence to the memory of the great men upon whose early labours they were now building, to the successful progress of those now striving in this field, and to the ultimate success of cancer research. The toast was briefly responded to in excellent English by Dr H T DEELMAN, Professor of Pathology in the University of Groningen, and Dr RAFFAELE BASTIANELLI, Professor of Surgery in the University of Rome, who each paid compliments to British work and British workers in the realm of cancer investigation. Mr W SAMUELSON HANDELY, Senior Surgeon to the Middlesex Hospital, in proposing the health of the many distinguished guests from abroad and at home, said that cancer could not be fought by a small professional army alone but was everybody's affair. Professor C REAULT, Director of the Radium Institute Paris replied in graceful terms in French, and Dr JAMES EWING, Professor of Pathology in Cornell University, who also responded said that it was now recognized that the cancer patient must be the subject of careful comprehensive study and consultation by workers in many departments of medical science. Sir JOHN BLAND SUTTON, Consulting Surgeon to the Middlesex Hospital and President of the Conference in proposing the health of the chairman, spoke of the great services given to the Middlesex Hospital by Prince Arthur of Connaught and other members of the Royal Family, and the CHAIRMAN, in his reply expressed the hope that this conference in London would advance materially the cause they all had at heart.

PUBLIC HEALTH TEACHING

A GUIDE TO COURSES AND TESTS

It is more than three years now since the Current Resolutions and Rules for Diplomas and Degrees in Sanitary Science, Public Health, and State Medicine, as adopted by the General Medical Council, came into operation. It is to be presumed that within that period the various teaching and examining bodies have either amended old ways or adopted new ones, with the object of giving due effect to the changed requirements. Many persons, interested either directly or indirectly in public health work, have doubtless speculated from time to time as to the probable scope of the new courses as contrasted with the old. Many young medical graduates, both at home and abroad, desiring to take a special qualification in public health, have felt the need of guidance and information as to the institutions which are best fitted to give the new teaching. The needs of both of these classes will be well served by the Guide to the public health regulations, courses, and examinations prepared with praiseworthy thoroughness by Dr. Andrew Balfour, and published by the British Medical Association.

It appears from this valuable compilation that degrees in sanitary science are conferred in England by the Universities of London, Durham, Liverpool, and Birmingham; in Scotland by the Universities of Glasgow and Edinburgh; and in Ireland by the University Colleges of Dublin and Cork. In London and Durham the course is one year; in Liverpool and Glasgow two years. It is advanced as a special feature of the London degree that its conditions preclude its being taken by a part-timer. This is true, but surely not distinctive. Any course nowadays, under the new regime which admits the part-timer to either a degree or a diploma in public health, must be rather illusory. In London a sanitary survey, in Liverpool a report on hygiene, and in Glasgow an investigation in applied hygiene form part of the course for the degree. These are special features.

Diplomas in Public Health are granted in England by the Universities of Oxford, Cambridge, Durham, Leeds, Liverpool, Manchester, and Birmingham, and by the English Conjoint Board; in Scotland by the Universities of St. Andrews, Glasgow, Aberdeen, and Edinburgh, and by the Scottish Conjoint Board; in Ireland by Trinity College, Dublin, the University Colleges of Dublin and Cork, Queen's University, Belfast, and the Irish Colleges; and in Wales by the University of Wales. The examination for the diploma, in terms of the regulations, is required to be in two parts, the second of which may not be taken prior to the completion of two years from the date of obtaining a registrable medical qualification. No partial pass in either Part I or Part II is permitted. In each part all the specified subjects must be taken and passed at one sitting. The course of actual study from start to finish must not be less than one year, and, given application and good fortune, need not exceed it.

One of the differences between the old system and the new is the reduction of the time devoted to chemistry. Another is the expansion of bacteriology to keep pace with progress. Another is the introduction of parasitology as a named subject, generally regarded as including protozoology, entomology, and helminthology. Another is the elevation of meteorology jointly with climatology into a subject of Part I in which a separate pass is required. The changes in Part II mainly consist in the more precise delimitation of subjects and courses, most of which had been previously taught. Dr. Balfour's comments upon the extent to which the teaching and examining bodies have complied with requirements under these heads are apt and to the point.

As regards his comparison of the universities and other bodies with one another, were it not for Dr. Andrew Balfour's modest disclaimer of any pretension to completeness, and his statement that here and there, with some object in view, he has considered it desirable to expand, the critical reader might be disposed to express surprise at the differences in the space which he has allotted in

different cases. He quotes some courses with a wealth of detail extending to a number of pages, and dismisses others with a summary. Some of the full descriptions cited are admirable, others are merely lists of the obvious. Dr. Balfour is inclined to allow credit to bodies which name port hygiene in their curricula, but for universities situated in maritime cities port hygiene is so much a matter of routine that it has not apparently occurred to them to mention it in their syllabus or prospectus. They have, however, themselves to thank if they have failed to receive their due. They should cultivate the art of self-expression.

The second part of this handy guidebook gives information about qualifications in tropical medicine and hygiene. A degree or diploma in tropical medicine is granted in England by the Universities of London, Cambridge, and Liverpool, and by the English Conjoint Board, and in Scotland by the University of Edinburgh. Among the institutions which provide qualifying courses is the London School of Hygiene and Tropical Medicine.

Dr. Balfour's compilation is a most helpful piece of work, and carries us as far as we can go for the time being. As the various courses proceed and develop the test of their merit will effectively be made in two directions: first by the judgement of the General Medical Council, which has more direct control over these curricula than over undergraduate medical teaching, and second, by the record of the various graduates or diplomates as they make their places in the administrative field. As regards the result of the former test we do not presume to speak, as regards the latter we hazard the conjecture that the public health courses whose scientific training is soundest and most exacting will, in the end, produce the medical officers best qualified to win distinction and serve the community in positions of trust.

ILLEGAL TRAFFIC IN DANGEROUS DRUGS

BRITISH REPORT TO THE LEAGUE OF NATIONS

THE report to the League of Nations by the British Government on the traffic in opium and other dangerous drugs for 1927 is accompanied by an official communique which states that the extent of the traffic illustrates the need for the application in all countries of the methods of control laid down in the International Opium Convention of 1925, which is discussed elsewhere in this issue (p. 117). Regarding smuggling the report records that there is nothing of special interest to relate in the year under review, during which there were a few unimportant cases. The communique, however, adds the information that two important seizures of smuggled cocaine have already been made in London this year. One consignment, of Japanese manufacture, was brought into this country by a lascari seaman, the other, of German manufacture, had been exported from that country to Lithuania, whence it was smuggled into Great Britain by a Lithuanian resident in London. Proceedings under the Dangerous Drugs Acts were initiated against 60 persons (compared with 95 in 1926 and 68 in 1925), of whom 45 were convicted and sentenced, or dealt with under the Probation of Offenders Act. The commonest offence was "unauthorized possession." No information was received during 1927 that any firm in Great Britain had been engaged in smuggling drugs abroad, nor have any seizures of drugs of British manufacture been reported.

In connexion with the international illicit traffic in drugs, information regarding 47 cases was transmitted to the League's Opium Advisory Committee, particulars being supplied also to any other Governments concerned. A large number of seizures were reported from British territories in the Far East. The direct interchange of information with other Governments proved valuable, and arrangements for an interchange agreement were made with the United States authorities. Action was taken in several cases to prevent vessels engaged in the opium traffic in Chinese waters from enjoying the protection of the British flag.

Statistics of the manufacture and export of morphine and heroin show that the production of morphine decreased from 97,502 oz. in 1926 to 80,103 oz. last year, and the export from 73,289 oz. in 1926 to 66,107 oz. last year. The production of heroin, however, rose from 11,113 oz. in

¹ Guide to Regulations, Courses, and Examinations for Qualifications in Public Health, in Tropical Medicine and Hygiene in Great Britain and Ireland. A Compilation and Brief Review, with Notes and Comments by Andrew Balfour, M.D., C.M.G., M.D., D.P.H. London: British Medical Association, 1928. (Post 8vo, pp. 176, 3s. net.)

1926 to 17,427 oz last year, and the export from 6,799 oz in 1926 to 11,165 oz last year. The export of heroin to France increased on the year by 4,610 oz, while the export of morphine fell by 5,595 oz.

Imports of cocaine amounted to about 16,000 oz. The report records the fact that for the first time in history the manufacture of cocaine by any firm in Great Britain has been permitted. During 1927 a licence to carry on experiments in the manufacture of this drug was issued to Messrs May and Baker, Limited, of Wandsworth, by the Home Office. The firm was not originally allowed to sell its product, but since the beginning of this year permission to do so has been granted.

STANDARDIZATION OF THERAPEUTICAL PREPARATIONS

THE League of Nations has just published the report* of this year's meeting of the permanent Commission on the standardization of serums, serological reactions, and biological products. The problems dealt with by the Commission are highly technical, for the bio-assay of drugs involves methods in which every detail has to be regulated exactly if reliable results are to be obtained.

The work of the Commission is, however, of great service to the medical profession. In the first place it secures international agreement regarding the units of measurement to be used. This alone is a great advance, for medical literature is international, and the use in works of reference of units which differ in value in different countries may lead to dangerous confusion. In the second place it is most important to have really trustworthy methods for measuring the activity of biological products, and the Commission is doing valuable work by its careful and critical examination of the numerous methods of standardization that have been evolved.

The following is a summary of the more important conclusions arrived at by the Commission.

I—STANDARDIZATION OF ANTIGENS AND ANTIBODIES

(1) *Anti diphtheritic Serum*

In view of new facts brought to light by the phenomenon of flocculation occurring in the mixture of specific toxin and anti diphtheritic serum the Commission decided to study the evaluation of anti-diphtheritic serum and of diphtheritic antigen (toxin and derivatives) by the flocculation method.

(3) *Anti tetanus Serum*

The Commission now proposes to adopt the following anti tetanic unit.

The unit is to be determined with a standard serum in such a way that its relation to the American unit is exactly 2 International to 1 American unit.

(4) *Anti dysentery Serum (Shiga)*

The Commission proposes to adopt a standard serum prepared and distributed by the Danish State Serum Institute to establish the international antitoxic unit.

The serum is prepared for distribution in such a way that 1 unit is contained in 1/200 of 1 c.c.m., and that a dilution in the proportion of 1:200 contains 1 unit in 1 c.c.m.

A test dose of a dysentery toxin shall be defined as such a quantity that, when 1 c.c.m. of this serum dilution is mixed with it, the mixture shall cause death in one third of the mice receiving it by intravenous injection.

When a toxin is standardized in this way it may be used in titrating the serums.

(8) *Blood Groups*

The Commission

learns with satisfaction that, on the initiative of the Health Organization of the League of Nations, the nomenclature proposed by von Dungern and Hirsfeld for the classification of blood groups has been generally adopted, and recommends that this nomenclature shall be adopted for international use, as follows:

O A B AB

To facilitate the change from the nomenclature hitherto employed the following is suggested:

Jansky	O(I)	A(II)	B(III)	AB(IV)
Moss	O(IV)	A(II)	B(III)	AB(I)

II Recommends the adoption of the following method of designating test serums:

Test-serum A (anti B)
Test-serum B (anti A)

II—STANDARDIZATION OF THERAPEUTIC SUBSTANCES BY BIOLOGICAL METHODS

(1) *Salvarsan*

The Commission endorsed the recommendation made at the Geneva Conference of 1925 with certain modifications. The chief alterations were that it was decided to recognize a test for experimental action on animals infected with spirochaetes as an alternative to that in which trypanosomes are used.

The Commission recommends that a 20 per cent excess of toxicity above that of the standard would be a suitable limit for tolerance. It also recommends that the standard samples for neosalvarsan and sulpharsphenamine provided by Professors Kolle and Vogtlin respectively for trial are suitable, as regards toxicity and experimental therapeutic activity, for adoption as the basis for the international standards.

(2) *Digitalis*

"No 3. The Commission considered that they had now sufficient evidence before them to justify a somewhat wider recommendation with regard to comparative methods of testing than that adopted by the Geneva Conference of 1925. It considered that the following methods might be recommended as suitable:

"(a) The frog method in the form recommended by the Geneva Conference, or in its other modifications.

"(b) The method using intravenous infusion in the mammal as described by Hatscher and modified by Magnus and his colleagues for the cat by Knäfl-Leuz for the guinea pig or by Tiffeneau for the dog.

"(c) The Commission considered that the methods described by Mansfeld, using portions of the isolated sinus venosus of the frog, and by Trevan using the isolated auricle of the rabbit merited further investigation with a view to consideration on a future occasion."

The Commission also recommended:

"That, when the dosage of digitalis or its preparations is expressed in units of activity, the unit employed for any preparation and in any country should be an international unit which should be defined as the specific activity contained in 0.1 gram of the international standard powder."

(4) *Insulin*

The Commission found that the results obtained by the use of the standard preparations recommended in 1925 were uniformly favourable, and that the unit adopted and recommended by the Geneva Conference of 1925 was now in use all over the world as the only unit of insulin. In view of this satisfactory position the Commission decided to adopt the recommendations of the Geneva Conference of 1925 as regards the standard of insulin without modification.

That the dry preparation of insulin hydrochloride, prepared by the Medical Research Council of Great Britain, at the request of the Edinburgh Conference should be accepted as the international standard preparation of insulin. That 1 milligram of this standard contains 8 units of insulin (or 1 unit=0.125 milligram), as provisionally defined by the Insulin Committee of the University of Toronto.

(5) *Pituitary Extract*

The Commission accordingly recommends, in the light of the uniformly favourable experience obtained since the Geneva Conference of 1925, that the dry preparation of the acetone-extracted fresh posterior lobe substance of ox pituitary be now definitely adopted as the international standard preparation for the biological evaluation of preparations of the posterior lobe of the pituitary body, whether containing all the active principles of the lobe, or the pressor or oxytocic principle only, in separate solution.

None of these conclusions requires much comment. In general it may be said that three years' experience in the use of the methods of standardization recommended at Geneva has shown that these are sound, and require only minor modifications.

It is interesting to note that as regards biological standardization experience has confirmed the finding of the Geneva Conference that the only sound method of standardization is to compare the activity of the preparation to be tested with a standard preparation of the same substance. For example, preparations of digitalis and the pituitary gland have to be standardized against standard preparations of these drugs, and experience has shown that it is not safe to attempt to standardize them against simpler chemical substances of known composition. For example, the methods by which digitalis was standardized against ouabain, and pituitary extract against histamine, are now recognized as unsound.

OXFORD OPHTHALMOLOGICAL CONGRESS

THE eighteenth annual meeting of the Oxford Ophthalmological Congress was held at Oxford on July 5th, 6th, and 7th. The attendance was well over a hundred, in matter for congratulation, since there were hardly any members from abroad present, owing, no doubt, to the fact that the International Congress of Ophthalmology will be held next year at Amsterdam. Members met informally at dinner on July 4th in the Hall of Keble College, which again offered its hospitality, as in former years. The advantage gained by residence in college, where each member is assigned rooms and becomes for the time being a student, is a prominent feature of this successful annual gathering of ophthalmic surgeons. When not occupied in the formal proceedings members exchange views on every aspect of the specialty, while friendships are formed or renewed in a manner rarely possible otherwise. This companionable informality is what was always in the mind of the founder of the congress, the late Robert W. Dayne, a brilliant and original thinker.

The proceedings of the congress were held in the Department of Human Anatomy of the University, kindly lent for the purpose by Professor Arthur Thomson, to whom the congress owes much. Year after year Professor Thomson has granted the use of his department, so that it may almost be regarded as the "home" of the congress. In addition to the scientific museum a commercial museum was established, in which fourteen well known firms of ophthalmic instrument makers exhibited the latest forms of apparatus and instruments.

ULTRA-VIOLET RAYS IN OPHTHALMOLOGY

The proceedings were opened on the morning of July 5th by a short address of welcome by the Master, Mr. PHILIP H. ADAMS, Reader in Ophthalmology in the University of Oxford. Immediately following this Professor LEONARD HILL opened a symposium on ultra-violet rays.

Professor Hill dealt with the biologically active rays, their measurement, and then penetration of the skin and eye, the theory of their action and of immunity to them, the comparison of sun and lamps as sources, and the action of rays as evidenced by erythema, he touched also on haemobactericidal power, rickets, ergosterol, vitamin D, and pigment formation. Some interesting slides of the effect of erythema by ultra-violet ray were shown.

Dr. G. M. B. DODSON discussed the effect of atmosphere, of the altitude of the sun, and of the presence of ozone on the transmission and the energy of ultra-violet rays. Curves and photographs illustrating these effects were shown. Dr. W. J. TURRELL related his clinical experiences of the practical administration of ultra-violet rays, emphasizing the importance of the regulation of dosage. The lamp he favoured was the tungsten arc lamp, which he had used for thirteen years. Mr. W. R. ACKLAND dealt with phototherapy in the treatment of dental disease, referring especially to pyorrhea and its relation to ocular diseases. Dr. N. S. LUCAS described his very interesting experiences of the treatment of rickets in marmoset monkeys by ultra-violet rays, using a mercury vapour lamp. An important point observed was the effect upon the eyes when exposed to the rays, a reaction came on much more rapidly—namely, in from one to two hours—than in the human subject, but passed off more quickly. Dr. Lucas considered that some ultra-violet ray dosage was essential to monkeys not living in their natural state. Mr. G. O. HUMF spoke on the local application of the rays to the eye in certain conditions, emphasizing the importance of selection of cases and dosage. Mr. A. F. McCILLAN, while recognizing the beneficial effect of phototherapy, urged the need for a continued search for causal conditions, notably septic foci in the teeth and tonsils. Owing to illness Mr. W. S. DUKE-FELDER was unable to be present, but his paper will appear in company with the full report of the proceedings of the congress in the *Transactions* of the Ophthalmological Society of the United Kingdom.

OPHTHALMOLOGICAL DEMONSTRATIONS

The afternoon of July 5th was devoted to demonstrations and the examination of ophthalmic apparatus in the scientific and commercial museums.

Mr. J. L. MADDON showed an accommodation balance test, a new fixation site for the globe in intracapsular cataract extraction, and an ingenious apparatus for training amblyopia in squint on a new principle involving hand and eye.

Mr. RAYNER BATES showed an interesting collection of fundus drawings of diseases and anomalies of retinal and choroidal vessels.

Dr. MARGARET DONKIN showed a test for astigmatism in which the diachrome principle was applied to the Maddox "V" test.

Mr. GEORGE YOUNG demonstrated the instruments he now uses in the operation of double sclerectomy for glaucoma which he has devised, and also a number of slides in which the effect of the operation could be seen.

Mr. W. NICCOLI showed slides of a carcinoma of the choroid secondary to carcinoma of the breast, and Mr. B. CRIMLAIN exhibited a test type for children.

The proceedings on the morning of Friday, July 6th, opened with a preliminary report by Mr. BURDON-COOPE on spectroscopy of the crystalline lens, in which he gave, with a lantern demonstration, the results of the spectroscopic examination of normal and cataractous lenses. The spectrograms showed that in cataractous lenses potassium was diminished and calcium increased.

Mr. T. HARRISON BUTLER read a paper on sympathetic ophthalmia, which was discussed by Messrs. S. H. BROWN, MALCOLM HENDER, H. M. TRAQUAIR, and A. W. ORMOND.

THE EYES OF BIRDS

Then followed the Dorne Memorial Lecture, which is undoubtedly the most important contribution to the proceedings of the congress. Instituted in 1916 in memory of the founder, the late Robert Walter Dorne, these lectures have proved the occasion for the appearance of much valuable and original work. This year the lecture was by Professor ARTHUR THOMSON, Lees professor of human anatomy in the University of Oxford, and was no exception to the rule.

Professor Thomson, who took for his subject observations on the eyes of birds, reviewed the literature of the past 250 years on the study of the pecten, and gave an exposition of the anatomy of this little understood portion of a bird's eye, aided by some excellent slides and models. It was shown that the most prominent portion of the pecten which projected furthest into the globe was more closely attached to the hyaloid membrane overlying it than it was at its sides. The hyaloid lying upon this black pigmented structure acted as a dark mirror, and Professor Thomson suggested that its function might very reasonably be one of elimination of dazzle from the direct rays of the sun, with reflection of objects from the upper field of vision to some other part of the retina. The value of this in the case of all birds other than birds of prey would be at once recognized. A bird of prey hovering with its back to the sun and in the region of dazzle so far as the ground bird was concerned was in a position of distinct advantage, while the latter with its enemy in the region of dazzle, and thereby difficult to see, was greatly handicapped. If, however, it was true that the bridge of the pecten was a dark mirror, which could eliminate dazzle and reflect the image of the prey-bird, Nature had provided the ground bird with a suitable means of defence.

Some excellent photographs were shown imitating these conditions as far as possible and undoubtedly supporting this fascinating and reasonable explanation of the function of the pecten. The subject is one which has received little attention since the days of Petit, some two hundred years ago, and Professor Thomson is to be heartily congratulated on his work. The lecture, delivered in a very clear and lucid manner, commanded the greatest attention, and at its conclusion Professor Thomson was presented with the Dorne Memorial Medal for the year.

VARIOUS PAPERS AND REPORTS

Mr G R DE BEER, lecturer in comparative and experimental embryology in the University of Oxford, then gave a most interesting paper on some original work on the development of the vertebrate eye. It was agreed that this paper was a most important contribution to the subject, and that its publication would enable it to receive the thoughtful attention it deserved.

On July 7th the session opened with a speculative paper by Lieut-Colonel HENRY SMITH, I.M.S. (ret.), on the nutrition of the lens and the vitreous. Comparing the uterus with its rhythmic contractions as a means of maintaining circulation, and thereby nutrition, he suggested that a sluice-like action of the ciliary muscle of the eye occurred whereby the canal of Schlemm and neighbouring spaces were opened and relaxed, so aiding the circulation of the aqueous humour.

Reports of a series of interesting clinical cases were then given by the following: Miss IDA MANN, a congenital abnormality of the retina; Mr JOHN ROWAN, a case of glomata of the retina (both eyes removed for glomata at 1 year and 5 months, no recurrence after over three and a half years); Mr GEORGE YOUNG, a case for diagnosis (enuresis up to the age of 17, which disappeared after correction of some hypermetropic astigmatism); Mr J A ROSS, keratitis with intranasal causation (keratitis of fifteen years' standing cured after treatment of an anterior ethmoiditis); Mr C G RUSS WOOD, case of Mikulicz's disease with complications; Mr W NICCOL, a case of recurring membranous conjunctivitis; and Miss MARION GILCHRIST, a case of keratitis marginalis profunda occurring in both eyes. All the cases were freely discussed by members.

SOCIAL EVENTS

At the conclusion of the afternoon's proceedings on July 5th members and their friends visited the gardens of Trinity College for tea, where they were welcomed by Professor and Mrs R A Peters, who kindly acted as host and hostess.

The annual dinner of the congress was held in the evening in the Hall of Keble College, and was unusually well attended. Among the guests were the Regius Professor of Medicine Sir E Farquhar Buzzard, K.C.V.O., Professor Arthur Thomson, Miss Kirkaldy, Dr W J Turrell, Dr G M B Dobson, F.R.S., and Dr N S Lucas.

Speaking on behalf of the congress, the Master, Mr PHILIP H ADAMS, mentioned that eighteen new members had been elected during the year, the total membership being now 414, including eight honorary members. The attendance at the meeting in 1927 was 104, and included many well-known ophthalmic surgeons from the Continent and America, some delegates had even come from Australia, India, and South Africa.

The toast of the visitors was proposed by Mr R J COULTER, who paid a tribute of thanks to all who had helped the congress in various ways. He referred especially to the interest which Professor Arthur Thomson had always displayed in the meetings since their foundation, and which had been no small factor in their success. In conclusion, he welcomed the Regius Professor of Medicine in this his first year of office, and coupled his name with the toast Sir E FARQUHAR BUZZARD, in acknowledgement, mentioned that not for 250 years—that is, since the Regius Professorship had been held by Dr Bailey—had there been one elected who was so closely connected with ophthalmology as himself.

On the afternoon of July 6th the scientific and commercial museums were again available, but as an alternative a visit to the Morris Motor Works had been arranged and the majority of the members availed themselves of the opportunity to see the mass production of motor cars.

It was generally agreed that this congress had been as valuable and as pleasant a meeting as had ever been held. Although its international character was less pronounced on this occasion than in 1927 yet the increase in the attendance of ophthalmologists from Great Britain and the maintained usefulness and interest of the discussions are matters for congratulation.

Nova et Vetera.

KIDNAPPING

In an article under the heading of 'Nova et Vetera,' entitled "A surgeon enslaved," in our issue of September 17th, 1927 (p. 511), an account was given of the way in which some of the prisoners taken at the battle of Sedgemoor were disposed of. There was nothing new in the proceeding which sent Henry Pitman a slave to Barbados. A large number of the Scottish prisoners taken at Dunbar by Cromwell were sent to the plantations of Virginia or elsewhere in America and Africa, and after the battle of Worcester the same method of disposal of prisoners was resorted to. Their lot—like that of all prisoners and captives in those days—was a hard one. It was referred to in moving terms by Sir Walter Besant in his book on Westminster. Speaking of Tothill Fields, now represented by Vincent Square, which is still known as "Fields" to all Westminsters, old and young, he wrote:

The saddest of all memories connected with Tothill Fields is that of the triumphal entry of Cromwell into London after the crowning mercy of Worcester. He brought with him the miserable prisoners he had taken on that field. There were four thousand of them in all. They camped at Mile End Green when Cromwell drove into London the next day they were marched right through the City and along the Strand to Westminster and so to Tothill Fields. On the way they received alms oatmeal and biscuit from any who were moved of their pity to bestow something upon them. So they lay in the marshy fields where many died until they were sold as slaves to the merchants of Guinea.

The churchwardens' accounts of St Margaret's Westminster, exhibit according to Wheatley and Cunningham's *London Past and Present*, a payment of thirty shillings to Thomas Wright, for sixty-seven loads of soil 'laid on the graves in Tothill Fields, wherein 1,200 Scotch prisoners, taken at the fight at Worcester, were buried.' How the prisoners from the Western Midlands came to be at Mile End on the east of London Besant does not explain.

Prisoners taken in battle, however, were only occasional windfalls to the American or African employer, and this source dried up after the revolution of 1688, for we do not hear of any large number of Jacobite rebels being transported after the rebellion of 1745. The regular supply of white labour was maintained by the transportation of criminals and by kidnapping young persons—indentured apprentices, the wiser called it—for which Bristol, then the great port for the American and African trade, became notorious. In that erudite and entertaining work *The Annals of Bristol in the Seventeenth Century* Mr Latimer has thrown a good deal of light upon this practice. It appears that in the year 1654 a corporate ordinance was adopted by the magistrates:

'It premises that many complaints had been made of the unreviling purloining, and stealing away boys maids and others, and transporting them beyond seas and there disposing of them for private gain without the knowledge of their parents and friends. This being a crime of much villainy it was ordered that all boys maids and others thenceforth transported as servants should before shipment have their indentures of service enrolled in the Tolsey Book. [The Tolsey was a kind of meeting place Exchange or Townhall.] A penalty of £20 was imposed on any ship captain or officer receiving persons not so enrolled. The offence was however too profitable to be suppressed by a mere by law and it is certain that kidnapping was habitually encouraged by many merchants throughout the century and was not uncommon even later.

Moreover when offenders were caught they were treated with remarkable leniency by a sympathetic bench, and it is therefore not surprising that the practice was persisted in. This infamous traffic had attracted the notice of the Privy Council. Mr Latimer states that:

In July 1680 their Lordships had received information that children were being daily snatched away from their parents and servants from their masters being caught up by merchants and ship captains trading to Virginia and the West Indies and there sold as merchandise. From the order which follows for the

searching of three ships then in the Thames and the rescue of the children they contained the system appears to have been as common in London as in Bristol.

The evil name of the Bristol Corporation in this matter of kidnapping did not escape the notice of Chief Justice Jeffreys. When he came to Bristol to carry out his mockery of a trial of the Sedgemoor prisoners he used the rough side of his very foul tongue on the mayor and aldermen.

"Sir, Mr Mayor you I mean, kidnapper! and that old justice on the bench, (Alderman Lawford) an old knave, he goes to the tavern and for a pint of sack he will bind people servants to the Indies! A kidnapping knave! I will have his ears off before I go forth of town."

It would be refreshing for once to feel sympathy with Jeffreys, could one but be sure that his indignation was genuine. He made the mayor enter the dock, and charged him and five aldermen with felony, but the prosecution seems to have been dropped, probably because the accused bribed the judge. It is well known that in this commission in the West Jeffreys made large sums from bribes received from wealthy prisoners.

In the seventeenth century Scotland had no share in colonial trade, but after the Union certain Scottish ports did a brisk trade with Virginia and the West Indies. It should be noted that in the sixteenth century, and later, the whole eastern seaboard of what are now the northern United States was included in the name of Virginia. In the eighteenth century kidnapping was frequent in Aberdeen. A strong light is thrown upon the state of things in that city by a curious pamphlet, published first in York in 1757, and entitled *The Life and Various Vicissitudes of Fortune of Peter Williamson, A Disbanded Soldier Containing a particular Account of the Manners, Customs and Dress of the Savages, etc., etc.* The author, who afterwards became well known in Edinburgh, was born in the parish of Aboyne, near Aberdeen, and when "under the years of pupillarity," probably at the age of 10, he was kidnapped—that is to say, he was enticed on board a vessel at Aberdeen, where he was detained with other children for about a month, until the ship sailed. She was wrecked "off Cape May near the Capes of the Delaware," but the human cargo was safely landed and finally taken to Philadelphia, where the captain sold them at about £16 a head. Peter was very fortunate in being bought by a certain Hugh Wilson, a North Briton, for the term of seven years. Wilson had himself been kidnapped from St Johnstone in Scotland, but had become well-to-do. "Happy was my lot," says Williamson, "in falling into my countryman's power, as he was a humane, worthy, honest man." The boy offered to serve for one year beyond his contract if Wilson would send him to school. To school accordingly he went every winter for five years. When he was 17, and his servitude presumably was over, his master died, leaving him £200 currency, worth about £120 sterling, his best horse, a saddle, and all his wearing apparel. After another seven years of various employment Peter married and settled down as a farmer near the forks of the Delaware river. At first all went well, but on October 2nd, 1654, when luckily his wife was away on a visit, he was attacked by twelve Indians, who offered him quarter and carried him off prisoner, having destroyed everything that they could not remove. At length he escaped from the Indians and joined General Shuley's regiment of the British army serving in America, from which he was invalided with a damaged hand after many strange chances, on its return to England, at Devonport.

"For want of a certificate from my Colonel or some other necessary qualifications," he says, "I could not get any provision made for me by pension or otherwise. Indeed as a reward for my sufferings and services I had the favour of a pass allowed and the sum of six shillings paid to carry me to Aberdeen about eight hundred miles only from the place where I was discharged."

Somehow or other he managed to get as far as York, where he got the first edition of his pamphlet (it contained 156 pages) printed as a means of making a little money which carried him on to Aberdeen. What happened on his arrival there is told in later editions of his *Life*, one of which "printed for and sold by the booksellers" in

Edinburgh in 1792, is now in the British Museum. The title-page runs as follows:

"French and Indian Cruelty/exemplified in the Life and Vicissitudes of Fortune of Peter Williamson/ who was carried from Aberdeea in his Infancy, and sold for a slave in Pennsylvania/ Containing/ The History of the Author's surprising Adventures in North America his Captivity among the Indians/ and Manner of his Escape the Customs, Dress etc of the Savages Military Operations in that Quarter, with a Description of the British Settlements, etc., etc."

"To which is added/ An account of the Proceedings of the Magistrates of Aberdeea/ against him, on his Return to Scotland, a brief History of his Process against them before the Court of Session, and a short Dissertation on Kidnapping."

It seems to have been reprinted often and to have become quite a popular chap-book in Scotland. The first (York) edition contained statements about his being kidnapped which grievously offended the merchants and Corporation of Aberdeen, who seized his books and had them burnt by the hangman, and put him in prison until such time as he should recant his statements about them. This he at length did as the only means of obtaining his freedom. He found friends in Edinburgh and able lawyers to take up his case. The result of his appeal to the Court of Session was that their Lordships were pleased on February 2nd, 1762, to pronounce the following interlocutor:

"The Lords having advised the state of the process and the libel relevant and proven and find the Defenders, conjunctly and severally, liable to the Pursuer in damages and modify the same to the sum of 100£ Sterling and decern and find the Defenders also conjunctly and severally, liable to the Pursuer in the expenses of the process, etc."

In vain the magistrates presented a reclaiming petition against this. A letter, signed by William Davidson and James Jopp, late bailies of Aberdeen, to Walter Scott, Writer to the Signet, has survived. In it they, of course, protest their innocence and ask his help, displaying a quite amusing dismay at the idea of having to put their hands in their pockets. This Walter Scott was the father of the novelist.

In his dissertation on kidnapping as practised at Aberdeen Williamson says:

"The trade of carrying off boys to the Plantations of America and selling them there as slaves was carried on at Aberdeen as far down as the year 1744, with an amazing effrontery. It was not carried on in secret or by stealth, but publicly and by open violence. The whole neighbouring country were alarmed at it. They would not allow their children to go to Aberdeen, for fear of being kidnapped. When they kept them at home, emissaries were sent out by the merchants who took them by violence from their parents and carried them off. If a child was missing it was immediately suspected that he was kidnapped by the American merchants and upon inquiry that was often found to be the case, and so little pains were taken to conceal them, when in the possession of the merchants, that they were driven in flocks through the town under the inspection of a keeper who overawed them with a whip, like so many sheep carrying to the slaughter. Even the tollbooth and the public workhouses were made receptacles for them and a town officer employed in keeping them. The practice was but too general. The names of no less than fifteen merchants concerned in this trade are mentioned in the proof."

In the *Social Life of Scotland in the 18th Century*, by Henry Grey Graham, vol. II, 1899, the practice in Scotland of selling children is said to have arisen out of the terrible poverty caused by the famine of 1740, at about which date Williamson was carried off. Mr Graham quotes entries in the *Book of Bond Accord* such as "To R. Ross for listing his son 1s. To Maclean for listing his son 1s. 6d." If these sums are to be taken as Scots currency, in which a shilling equalled an English penny, the poverty of the people is terribly emphasized.

The *Dictionary of National Biography* tells us that Peter Williamson was successful in a second suit brought in 1765 against the parties engaged in kidnapping. He settled in Edinburgh and became a bookseller and printer, and keeper of a tavern known as "Indian Peter's Coffee Room." In 1773 he issued the first street directory of Edinburgh. He also published a weekly periodical, *The Scots Spy or Critical Observer*, and later *The New Scots Spy*. He established a penny post, which was taken over by the Government in 1793, for which he was awarded a pension of £25 a year for life. He wrote many pamphlets. A portrait of him in the dress of a Delaware Indian is affixed to the *Life*

British Medical Journal.

SATURDAY, JULY 21st, 1923

THE PROBLEM OF SERUM SENSITIZATION

WHEN giving antitoxic serum the medical practitioner has always more or less definitely in his mind the possibility of "anaphylaxis." The phenomena of anaphylaxis in the guinea pig are well known and fairly well understood. A guinea-pig which has been "sensitized" by the injection of any foreign protein such as horse serum will, if injected several weeks later with the same protein, die in a few minutes with intense dyspnoea. It was at first generally assumed that human beings would be affected in the same way, and great fear of sensitization by the administration of serum arose. Experience has, however, taught that the average human being is incomparably less prone to develop anaphylaxis than the guinea pig. In years past large numbers of people have been inoculated more than once with diphtheria antitoxin for protection against diphtheria; many soldiers were given antitetanic serum repeatedly at long intervals during the war, yet anaphylactic death, with the characteristic sudden dyspnoea, was very rare. Louis Martin,¹ after the war, went so far as to express his conviction that repeated subcutaneous injections of serum never provoked those grave anaphylactic crises in man that have been produced experimentally in guinea pigs. Lamson,² who reviewed the literature in 1924, points out that most of the rare tragically sudden deaths that startle the physician follow a first injection of even small amounts of serum in those peculiar individuals who have a natural intense sensitiveness to horse serum. Boughton³ records death in less than an hour following the intravenous injection of 5 minims of horse serum into an asthmatic subject, such patients are always liable to manifest acute or even fatal dyspnoea after injection of serum. Other authors⁴ describe sudden death after the intramuscular injection of a few cubic centimetres; Park⁵ found seven instances amongst 350,000 injections of diphtheria antitoxin—that is, 1 in 50,000—and some figure of this order agrees with general experience. But dangerous sensitization by a previous dose of serum, though it must be very rare indeed in human beings, far rarer than is generally supposed, does occur. Careful records of deaths following the re-injection of serum into patients who had shown no unusual symptoms after the first injection have been published by Tuft⁶ (first reinjection) and Dean⁷ (fourth reinjection).

What, then, is the practitioner to do when, for example, a child who has received scarlet fever antitoxin some months previously is admitted with severe diphtheria and antitoxic serum clearly must be given? Can he test whether the child is sensitive, and, if so, can he desensitize? It was at one time hoped that the response to a drop of serum injected intracutaneously would give satisfactory guidance, but unfortunately, though it is broadly true that patients whose skin shows a positive reaction with oedema and flushing after the intradermic test are more likely to suffer from urticaria and arthralgia some seven days after the injection of serum than those showing no reaction, this is not as Park⁸ pointed out, an invariable rule. Some who show a positive

reaction take serum without incident, others who fail to react may, when given the main dose of serum, become alarmingly ill. Coca,⁹ who probably goes further than most would follow, writes "It is useless to apply the cutaneous test or the procedure of sensitization." An anaphylactic guinea pig can be desensitized by careful dosage, and it has been assumed that by several half hourly subcutaneous injections of serum human beings also may be desensitized. There does not seem, however, to be any satisfactory evidence that this is true. Indeed, Blankenhorn¹⁰ and Tuft,⁶ who reviewed the literature, recorded instances in which the procedure definitely failed. But it may be anticipated that the injection of 0.5 c cm of serum subcutaneously an hour before the main dose will justify itself in practice, not as a method of desensitization, but as a test for extreme sensitivity. It is probable that those few patients in the past who died after the injection of a few cubic centimetres intramuscularly would have been detected had this test been known and used. Where intravenous injection is in question Besredka¹¹ recommended the gradual introduction of large quantities of saline solution, the first volume of 1 c cm which flows into the vein containing perhaps 0.1 c cm of serum and the next twice as much. An injection of a dose of 50 c cm of serum would require from half to one litre of saline solution, and would probably take an hour. Tuft recorded an instance which suggests strongly that if it is proposed to give serum intravenously—and the wider use of this method would probably reduce the present death rate from diphtheria—no trust can be placed in a preliminary subcutaneous injection of a small quantity of serum, an intravenous sensitivity test appears to be required. Besredka's method may be adopted, or 10 c cm of saline solution containing 0.1 c cm of serum may be injected intravenously an hour before the main injection. We may conclude that the practitioner pictured above would inject half a cubic centimetre of serum subcutaneously and, in the absence of alarming symptoms within an hour, would give his main injection intramuscularly. If he decided that intravenous injection was necessary his preliminary test must be an intravenous one. Should his patient prove to be acutely sensitive the doctor has an anxious prospect, and if he cannot avoid giving serum he has no alternative but to introduce it very slowly, avoiding the intravenous or intrathecal routes. It may be pointed out in passing that it is a wise precaution to have adrenaline always available for immediate use, either intramuscularly or intravenously, should disconcerting symptoms arise, for an injection of 1/2 to 1 c cm of the usual 1 in 1,000 solution may abolish the dangerous respiratory symptoms almost instantly. Adrenaline also has been used in the treatment of serum sickness arising a week or more after an injection.

Problems of sensitization arise also in connexion with the use of toxin antitoxin mixtures in America, and toxoid antitoxin in England, with which large numbers of children have of late years been injected. The amount of serum in 1 c cm of the prophylactic is usually one thousandth of a cubic centimetre or less. Several American writers have described in persons who had previously been immunized with toxin-antitoxin mixture immediate reaction (Stewart¹²), severe local reaction to intradermic serum injection (Lathrop¹³) a superficial local necrosis—the Arthus phenomenon (Gatewood and Baldrige¹⁴)—or a high percentage of serum sickness a week after the administration of serum (Gordon¹⁵). Exact details of the composition of the prophylactics and the serum used

by these authors are not given. It is evident that this suggestion that the injection of toxin-antitoxin mixture causes dangerous sensitization is not generally accepted in the United States. W. H. Park, who has had experience of 800,000 Schick tests or immunizations in New York, tested by the intradermic serum method children who had been immunized with the New York mixtures. He confirmed the finding that an increased percentage showed a positive reaction, but is of opinion that the sensitization given by toxin-antitoxin is in all probability a clearly negligible factor and that any fear of apparent sensitization may be dispelled from the mind of physicians. Dr. Sophie Spicer,¹⁰ working in the Willard Parker Hospital in New York, has recorded the results of injecting concentrated serum into 237 successive patients; serum sickness followed in 13 per cent of 164 patients who had never received serum injections or toxin-antitoxin mixture, in 17 per cent of 45 patients with a previous experience of antitoxin injection, and in 14 per cent of 28 children who had previously received toxin-antitoxin prophylactic. So far as we can trace, no similar groups of figures have been published in this country, but inquiries addressed to several experienced superintendents of hospitals for infectious diseases lead us to believe that the figures given by Spicer, and not the higher figures quoted by Gordon, would represent the average experience in Britain. There is here no evidence that the administration of mixtures of the type used by Park or of the English toxoid-antitoxin prophylactic produces any sensitization, in the sense in which this word is ordinarily used in everyday medical practice. Some of the American writers suggest the use of toxoid alone or of sheep and goat antitoxin in mixtures. Formalinized toxin—that is, toxoid or anatoxin—is being tried in America and England, and has been used on a considerable scale in Europe.

OUR BRETHREN OVERSEAS

In another part of this issue Mr. Victor Bonney gives an eloquent account of his experiences in New Zealand and Australia, to the former of which Dominions he went, as official delegate of the British Medical Association at home, at the conference of the New Zealand Branch in February last. His is the latest of a number of successful visits which have been paid overseas by representatives of the Association, with the intention of maintaining contact and strengthening and multiplying the bonds between the profession at home and in the Dominions. In 1914 the late Dr. J. A. Macdonald, then Chairman of Council, paid an official visit to Australasia which had the happiest effects, and after the war, in 1920, he visited South Africa on his retirement from office. The visit of that great surgeon Sir William MacEwen to Australia just after the end of his year of office as President of the Association, could not fail to

assure the members of the profession there of the regard felt for them by those at home. He was warmly welcomed at the first Australasian Medical Congress in Melbourne and later in New Zealand. At the next Congress, in Dunedin in 1927, Dr. Cooper Paton of Norwich represented the Association. In 1924 the visit of Sir Jenner Verrall and the Medical Secretaries, Dr. Alfred Cox, to Canada did much to bring about that affiliation between the Canadian Medical Association and the British Medical Association which will be cemented by the Annual Meeting at Winnipeg in 1930. Again, Dr. Cox's tour of the Union of South Africa during the winter of 1926-27 was largely instrumental in the formation of the Medical Association of South Africa (British Medical Association) out of the two pre-existing rival bodies, and in the early part of this year the present Chairman of Council, Dr. Brackenbury, visited that Dominion and further strengthened the ties between us.

This brief record of recent official visits shows that the Association here has been awake to the need of maintaining official personal contact with our brethren overseas, but we agree with Mr. Bonney that more than this is needed. Australia and New Zealand are, as he points out, much nearer in distance to the United States than they are to Great Britain, and America can in some sort be considered as the half-way house on the journey between the Antipodes and this island, so that there may be some danger that the spiritual home of Australasia may some day be transferred from Europe to America. It must be admitted by all of us that such a transfer would be regrettable, for the people of Australia and New Zealand are of almost pure British inheritance, while the population of the United States has for some time ceased to be predominantly British in blood. More and more, in all probability, will the Southern European elements in the United States assert themselves in future generations, despite the present regulation of immigration by means of quotas. Australians and New Zealanders show in many ways their affection for the Old Country. Many of them come here to complete their professional education and many of them have earned our respect and affection and proved their worth as holders of posts in our hospitals. Sentiment, however warm and sincere, must nevertheless in the long run be vanquished by self-interest, and if young medical men from overseas do not find what they want here they will seek it elsewhere. The most crying professional need in this country is for a post-graduate hospital and school whither not only visitors from overseas, but our own graduates, could resort for the higher medical education. In New York there is a large and well equipped post-graduate hospital, and the Johns Hopkins Hospital in Baltimore, of world wide fame, also offers openings to graduates. Here in London the Fellowship of Medicine is worthy of support as a co-ordinating body, but its scope is too limited at present.

Mr. Bonney comments on the small number of British practitioners who visit Australasia as compared with the number of Australasians who come to these islands. It is not to be expected that the numbers of visitors from both sides should balance, but there is no doubt that the disproportion should be reduced. The inducements which New Zealand offers to the visitor are either little known or little understood here. The most beautiful and varied scenery of mountain, lake, forest, and river, with volcanic phenomena which are of great interest without danger, and with a temperate climate comparable with our own but more sunny—all these and more will well repay a visit, to

six nothing of the warm welcome which the medical tourist may safely count upon from our professional brethren overseas. No doubt the length of the sea voyage, and consequent time occupied in travel, has deterred tourists from going to Australasia, but if the aspirations of armen are fulfilled it may soon be possible to make the journey between London and Auckland in as many days as it now takes weeks. In the meanwhile, we may be sure that the Council of the British Medical Association, with so many proofs before it of the value of official visits, will not be behindhand in furthering this good work on behalf of professional solidarity throughout the Empire. The Council is always on the look out for prominent members of the Association who are thinking of visiting the Dominions, as it is often possible to nominate them as official delegates, and thus not only benefit the Association, but add much to the personal comfort and education of the visitors themselves.

INTERNATIONAL CONTROL OF THE TRAFFIC IN DANGEROUS DRUGS

According to the last report of the Advisory Committee of the League of Nations on the traffic in dangerous drugs, it is anticipated, as recorded in our issue of June 30th (p. 1119), that the Convention drawn up at Geneva in February, 1925, "may begin to operate before the end of 1928." It will be remembered that this Convention was the outcome of the prolonged and contentious "second conference" held at Geneva in 1924-25 to implement the provisions of Chapter III of the Hague Opium Convention of 1912, which dealt with the control of traffic in medicinal opium, morphine, cocaine, heroin, etc. The later Convention was not to come into force until it had been ratified by ten Powers, including seven of the States in respect of which the proposed central board is to be appointed two of these to be Powers having permanent seats on the League's Council. When the Advisory Committee made its last report fifteen ratifications had been received four being those of members of the Council, including France and Great Britain, which are permanent members. It was then anticipated that Canada, the Netherlands, Japan, Switzerland, and Rwanda would shortly deposit their instruments of ratification. The central control board, when constituted, is to consist of eight persons to be appointed by the Council of the League, the United States, and Germany. This board is to collect information as to the amount of drugs required for medical and scientific purposes in each country for internal consumption, and also as to the raw materials imported, the amount of drugs manufactured, and the stocks in hand. If excess of stock is proved export to such country is to be suspended. Import and export of the drugs are to be effected only under Government certificates. Factories are to be licensed, and persons engaged in the traffic registered. The board is to receive statistical and other information annually from the contracting parties: it may ask for explanation of, and call attention to, illicit or excessive traffic, and may make recommendations as to the limitation of traffic, while a Government not disposed to act on the recommendation may invoke the Council of the League. The Advisory Committee is of opinion that "very little progress can be made in the direction of suppressing illicit traffic until the Convention of 1925 comes into force." This traffic "continues on an enormous scale," and the position in regard to it "is still highly unsatisfactory." The committee are still very imperfectly informed as to the manufacture of morphine and the sources from which illicit traffickers in this drug draw their supplies." While much is hoped for from the setting up of the board as the "mechanism for realiza-

tion" of the Geneva Convention, which "mechanism" the Hague Conference was by instructions precluded from discussing, it must be remembered that such producing countries as Turkey and Soviet Russia are not members of the League, and that "it is particularly unfortunate that certain (other) producing countries, as Bolivia, Greece, Peru, and Persia, have not yet seen their way to supply the committee with information." It is satisfactory, however, to note that a point of procedure, upon which the Italian delegates, Messrs Cavazzoni and Scialoja, have insisted, has been satisfactorily settled, and further, that the close association of the central board with the secretariat of the League is to be secured by making the secretariat of the former an integral part of the latter, and by the provision that the staff, nominated by the board, are to be appointed by the Secretary-General of the League and subject to the approval of the Council.

THE OSLER CLUB

THE anniversary of the birthday of Sir William Osler was celebrated in London on July 12th by the Osler Club. This club, which was founded in his memory and under the inspiration of his writings in April last for the study of the history of medicine, entertained a number of guests at an informal meeting. A reproduction of the Sergeant crayon sketch of Sir William Osler, lent by the Royal Society of Medicine, occupied the place of honour, and through the kindness of several London librarians pictures of the triumvirate of British Medicine—Linnæus, Harvey, and Sydenham—were displayed, together with some of Osler's favourite books—*Religio Medici*, the *Anatomy of Melancholy*, *Lettres de Gui Patin*, and works by the Swiss Osler, Conrad Gesner. Sir Wilmot Herringham, delivering the first Oslerian Oration, spoke of Osler's love of rare cases, not because they represented extremes of normal physiology, but because their rarity appealed to him as an artist. He told how the young Osler, inspired by the German educational "system" and by what he had seen of practical training here, completely altered the outlook of medical teaching in America, how later he was responsible for the establishment of clinical units in this country, and of his part in the launching of the *Quarterly Journal of Medicine*. Dwelling happily on Osler's personal charm and affectionate nature, Sir Wilmot Herringham closed a speech notable for its genuine feeling and its dignified simplicity. Dr. McEwen, representing the German Ambassador, in proposing a vote of thanks, wished particular success to a club one of whose aims was the promotion of international goodwill, and the name of whose patron saint was held in such reverent esteem in Germany. Sir Humphry Rolleston pronounced his Oslerian Eulogy on "Osler as a human being." It was, he said, the combination of so many different personalities in one body that made Osler the beloved man that he was. No report could do justice to the charm of the eulogy, the final words of which summed up the spirit of the whole evening—"We shall never look upon the like of such a man again." Professor D. Fraser-Harris opened the symposium with a paper on Osler as physiologist. Dr. H. H. Scott spoke on Osler as naturalist and comparative pathologist, Dr. Andrew Balfour on Osler and tropical medicine, Sir Squire Spriggs on Osler as a literary man. Sir Walter Fletcher on Osler as a friend, Dr. Franklyn Martin President-elect of the American College of Surgeons, on Osler as an organizer, Dr. J. D. Rolleston on Osler as epidemiologist. Dr. Friest Jones brought the symposium to a delightful conclusion with some personal reminiscences. The exhibition of a selection of Osler's writings, literary and scientific, of biographical appreciations, and of books inspired by him, bore further witness to the breadth of the man and to the

many-sided nature of his interests and enthusiasms. Among other guests of the club were Sir Thomas Lewis, Dr. Burton Haseltine of Chicago, Messrs. Geoffrey Keynes and S. Damiani, Dr. Henry Viets of Boston, and Mr. Philip Franklin.

ANAEMIA IN INFANCY

In the June issue of the *Archives of Disease in Childhood* Dr. Helen Mackay describes the results of a most extensive investigation of the anaemias of infancy between October, 1925, and December, 1927. Four groups of cases were taken: (1) artificially fed infants without special treatment, (2) breast-fed infants, (3) infants receiving light therapy, and (4) infants under treatment by iron. 541 infants were observed, and 2,561 haemoglobin estimations were made. The economic status of the infants selected was very poor, their ages varied from 3 weeks to 18 months, none being over 2 years at the end of the period of observation. Their general physical condition was subnormal, but no infants with acute illnesses were included. Dr. Mackay came to the conclusion that there was a typical haemoglobin age curve for the first year of life. Shortly after birth the haemoglobin fell steadily up to the age of 2 months. It then improved up to the age of 5 months, after which it declined steadily up to the age of 1 year. All the children investigated showed a very gross anaemia, in fact, in very few cases was the haemoglobin more than 75 per cent. The author concluded that the normal haemoglobin percentage in the blood in infancy from 4 months upwards was about 80 per cent, as estimated by Haldane's haemoglobinometer. She emphasizes the fact that the majority of artificially fed infants and many breast-fed infants in London are anaemic, and that treatment with a mercury vapour quartz lamp did not prevent or cure this anaemia, which was similarly unrelieved by outdoor life. The anaemia developed on a large variety of diets, and there seemed no relation between it and vitamin deficiency. It appeared to be definitely due to an iron deficiency, and Dr. Mackay was able to cure it by a soluble iron salt given by the mouth. Iron and ammonium citrate was administered in doses of from 4½ to 9 grains daily, this was either dissolved in the milk feed or was given incorporated in the dried milk, so that in measuring the milk powder the mother included a portion of iron in it. The effect of this soluble iron on the infants investigated was striking, and the percentage of infants reaching 80 per cent of haemoglobin was eleven times as great in the group receiving the medicated milk as in the control group. The author concludes that iron should be administered to artificially fed infants from the first months of life, and especially to those who are small at birth. Such iron-fed infants showed improvement in general health and resistance to infection, in this group the incidence of infection was only half that in the control group. The practical suggestion of the author that iron should be incorporated in dried milks by the manufacturers is of considerable interest. Doubtless the manufacturers only require a lead from the medical profession, and confirmatory evidence of Dr. Mackay's experience, before they embark on the "ironization" of their wares.

THE DEVELOPMENT OF FILARIA PERSTANS

ONE by one the filaria worms parasitic in man have yielded up the story of their life-cycle as the result of patient work of scientists in the tropics. The first to do so was *Filaria bancrofti*, which, as the result of Manson's brilliant hypothesis, was found to be conveyed from man to man by the common mosquito—a hypothesis, incidentally, which proved to be the starting point of the development of the whole modern science of tropical medicine. This was

followed by the work of Leiper, and later the Connals, on *Filaria loa*, the cause of Calabar swellings, which proved that this species reached its infective stage in certain species of Tabanids. Two years ago Blacklock was able to demonstrate that the nodular worm (*Filaria colubilis*) had as its vector a minute fly called *Simulium damnosum*. The life story of the last of the common filarial worms in man—*Filaria perstans*—has now been unravelled by Dr. Dyeo Sharp, working in the British Cameroons. This is the persistent filaria found by Sir Patrick Manson in the blood of an African negro in London nearly thirty years ago. Unlike *Filaria nocturna* (*F. bancrofti*), the larvae of which appeared in the blood stream mainly at night, and *Filaria diurna* (*F. loa*), the larvae of which appeared by day, this species could be found at any hour, although it is true that it was rather more numerous, as a rule, at night. It is, moreover, essentially a parasite of dark-skinned races, and is rarely, in West Africa at least, found in white men. From this fact Dyeo Sharp deduced that, since day-biting flies and night-biting mosquitos attack all colours impartially, the vector must be an object to light even at night, and so, with the assistance of his native boys, he commenced a search for such a fly, which he almost immediately found in the local species of *Culicoides*—a minute midge less than two millimetres long, with a hump back and dappled wings. This species objected to even one-quarter of a candle power at a distance of seven feet, it exhibited a decided preference for a black skin, and refused to feed, even when hungry, on a white one. Using native boys as the hosts, the flies were readily infected, but difficulties were immediately encountered in keeping the flies alive in captivity. Even after the necessary information about feeding and housing was acquired, trouble was caused by ants. To avoid these pests the cage containing the flies was suspended from a string, but the ants dropped off the ceiling and, climbing in, removed the flies! Finally, success was obtained by the use of test-tubes plugged with cotton-wool. In the *Culicoides* the life-cycle appears to be similar to that of the other filariae. The microfilaria becomes very active immediately after entering the stomach of the insect, and within six hours after ingestion it moults and passes into the stomach wall or fat-body. Its movements become lethargic and its body shortens and broadens at first, but later increases greatly in length. As it grows older the larva migrates into the thoracic muscles, and finally, in seven to nine days, reaches the head. When the fly bites a host the larva passes down the proboscis, the distal end of which it dilates and finally ruptures. How it actually enters the host, and, once there, how it reaches its adult habitat at the root of the mesentery or in the peritoneal tissue, is a problem which has still to be solved.

THE ROCKEFELLER FOUNDATION AND THE ROCKEFELLER INSTITUTE

THE review of the activities of the Rockefeller Foundation during 1927 by its president, G. E. Vincent, and an account of the organization and equipment of the Rockefeller Institute for Medical Research,² recently issued, show the admirable manner in which the funds of this wonderful benefaction are utilized in very widespread directions. During 1927 more than 11 million dollars were distributed in various ways, the last of these twenty categories being surveys of health conditions and of medical and nursing education in no fewer than fourteen countries. The question whether chief reliance should be placed upon private initiation and management, as in the United States, or upon Government control, as in Russia, is discussed, and it is then pointed out that the health of the

¹ *Archives of Disease in Childhood*. Issued by the British Medical Association. Yearly subscription (six numbers) 5s., a single number 6d.

³ The Rockefeller Foundation. *A Review for 1927*. By George E. Vincent, President. New York, 1928. (Pamphlet pp. 64 illustrated.)

⁴ The Rockefeller Institute for Medical Research. *Organization and Equipment*. New York, 1928. (Pamphlet pp. 25, 2 plates.)

public is primarily a governmental responsibility, and that the policy of the Rockefeller Foundation has from the start been to build up official health organizations by government authorities—national, state or provincial, and local. An account follows of the emergency relief given in connexion with the devastating floods in the lower Mississippi basin in 1927, where at one time more than 600,000 persons were dependent upon public support. The Foundation gave 2 million dollars to enable the Bloomsbury site to be acquired by the University of London, and so to erect "a shrine of learning worthy of the city and of the academic traditions of England." The account of yellow fever research contains a sympathetic notice of the late Professor Adrian Stokes. In a section headed "The migration of man and the spread of ideas" it is mentioned that in 1927 funds for fellowships were given to 864 persons from fifty-two different countries. The Rockefeller Institute for Medical Research is divided into three departments—the general laboratories, the hospital under the direction of Dr Rufus Cole, and the department of animal pathology, over which Dr Theobald Smith presides. Dr Simon Flexner directs both the Institute as a whole and the general laboratories, which are grouped in several divisions and subdivisions, thus subdivisions in pathology were conducted by Dr Noguchi, whose recent death from yellow fever is a terrible blow to medical science, by Drs Peyton Rous, Olitsky, Sabine, Cowdry, and Gates. The main problems now under investigation at the Rockefeller Hospital are the acute respiratory diseases, acute rheumatism, cardiac disease, nephritis and blood chemistry, respiration, and chicken-pox.

THE MAN WITH THE BARROW

CONTINUING its efforts to lighten the burden of human labour in industry, the Industrial Fatigue Research Board has published a report entitled *The Physiological Cost of the Muscular Movements Involved in Barrow Work*,¹ by Dr G. P. Crowden. Two earlier reports conducted for the Board dealt with the carrying of loads by hand, one of them, relating to the physique of women in industry, was discussed in our issue of December 17th, 1927 (p. 1155). The preface to the report under review disarms one of the most obvious criticisms that might be directed against the choice of such subjects for research—that the amount of purely manual labour is constantly decreasing with the extended use of labour-saving appliances and mechanization generally—by the statement that there remain many occupations, especially within the "heavy" industries, in which the demands made on the worker are mainly muscular. Dr Crowden's paper deals primarily with the physiological cost, as measured by oxygen consumption, of the muscular effort involved in heavy barrow work in the movement of bricks. His experiments were carried out near Peterborough, and his recommendations have been subjected to the test of actual working conditions, with satisfactory results. In effect the report offers a technique for barrow work, with details regarding the design of the vehicle used, the most favourable relation between its dimensions and the stature of the worker, the optimum load and best method of arrangement, the speed in transit, and the general working conditions. To the man in the street barrow work is just barrow work to Dr Crowden it has presented a whole series of physiological and mechanical problems requiring scientific investigation. Doubtless research on similar lines in other directions would bring about a very considerable amelioration in the lot of the manual labourer, and a substantial economy in effort. There is, however, one factor which seems to lessen the practical value of such investigations. It was found,

in the brickworks in the area where these experiments were made, that with a normal load there was one method of arrangement which was invariably adopted by the workers. Now it is true that in this case, as the result of the inquiry and subsequent recommendations, workers are being advised to vary the load arrangements as suggested in the report. The fact that until outside influence had been brought to bear neither the workers nor the management had apparently considered the possibility of change, serves to remind us how intensely conservative most men are with regard to their working methods. No one will suggest that such investigations as Dr Crowden's, which appear to have been executed with laborious care and considerable ingenuity, are superfluous, but at the same time it is impossible to escape the conclusion that much good work of this nature is wasted, owing to the reluctance of those most directly concerned to profit by the fruits of scientific effort. It is probably easier to show that, as in the present case, the comfort and efficiency of barrow workers can be improved by taking thought than to convince employers and workmen that this is so.

OPHTHALMOLOGY IN EGYPT

Mr A. F. MacCALLAN, who was for long Director of Egyptian Ophthalmic Hospitals, communicated at the end of last year to the *British Journal of Ophthalmology* an interesting article on the history of ophthalmology in Egypt. Much of the material under review was collected by Dr Meyerhof, whose researches were presented to the annual congress of the Ophthalmological Society of Egypt. The record of mediæval times is of particular interest, for in these we see the gradual appreciation of the grossness of eye disease, so common in that land. In 1598 a Bohemian doctor visited Cairo, and first described the masses of flies on the eyes of the children, and expressed the opinion that the flies were the cause of the ophthalmia, "as they soil, eat, and infect them." A Frenchman in 1745 dubbed Egypt the "land of the blind." In the nineteenth century Europe knew only too well the ill effect of Egypt upon the eyes, for nearly all the European armies that sojourned there during the Napoleonic wars were attacked, and many of the soldiers brought back the disease to their home lands. It was a mixture of trachoma, blennorrhoea, and more harmless forms of conjunctivitis, probably due to infections by the Koch-Weeks bacillus. The Italian and German oculists shared the British opinion as to the contagious nature of the disease, which was constantly denied by the French and by several of the Belgian and Russian observers. The French scholars who accompanied Napoleon found no trace of scientific medicine in Egypt, the old Arab traditions had been lost. There was a hospital in Cairo—the only one in Egypt—which had been founded in the thirteenth century, it was a dirty prison where a few insane patients were kept in chains and treated with whips. The French introduced sanitary institutions, but as soon as they left the country these were all destroyed. To Mohammed Ali, the Albanian adventurer who became Pasha of Egypt and founder of the present dynasty, belongs the credit of beginning modern sanitation in Egypt. He had his daughter vaccinated after Jenner's new method, and by spreading vaccination attacked one of the principal causes of blindness. The needs of his army demanded a sanitary service, and this was organized for him by a Frenchman, Clot, who founded a large military hospital and medical school. So great was the prejudice that Clot's life was attempted in the anatomical theatre while he was performing an autopsy. Clot adhered to the non-contagious view of ophthalmia and plague, and himself suffered seventeen attacks of ophthalmia during his twenty-five years' residence. To him is due the credit of introducing silver nitrate and sulphate of zinc into the therapy of eye diseases. German influence was mainly dominant

¹ *The Physiological Cost of the Muscular Movements Involved in Barrow Work*. By G. P. Crowden, M.Sc. M.R.C.S. L.R.C.P. Industrial Fatigue Research Board Report No. 50. London: H.M. Stationery Office, 1928. 1 net.

between 1850 and 1880 Koch, during the study of cholera in Alexandria, not only discovered the comma bacillus, but found the gonococcus in many cases of summer ophthalmia, and also discovered the Koeli-Weeks bacillus, which was at one time thought to be the cause of trachoma. Morax of Paris, working in the same city a few years later, found another organism, which is the cause of a specific form of chronic inflammation of the conjunctiva—the Morax-Axénfeld bacillus. Subsequently there came the British period of organization, marked by the gradual spread of hospitals over the land and the introduction of travelling clinics, financed out of a fund provided by Sir Ernest Cassel. Now there are a hundred ophthalmic surgeons in the country, and in recent years there has been a notable decrease in the number of blind persons.

PAY BEDS IN LONDON HOSPITALS

THE Pay Beds Committee, appointed by King Edward's Hospital Fund for London in May, 1927, has issued its report this week.¹ The committee consisted of the late Viscount Hambleden (chairman), Sir John Ross Bradford, President of the Royal College of Physicians, Sir Bernard Mallet, Mr V. Warren Low, F.R.C.S., and Professor Winifred Cullis, D.Sc. Its reference was to inquire into the question of hospital accommodation in London for persons prepared to pay more than voluntary hospital patients. The report strongly recommends the provision of beds on an extensive scale at from 4 to 6 guineas a week for the benefit of the professional and middle classes, whose position as regards medical attention in serious illness is much worse than that of the poorer classes. There are at present 1,055 pay beds in the London hospitals, a larger number than is generally supposed but still falling far short of the requirements. The committee recognizes that this shortage cannot be met at once, and it suggests a steady extension of present accommodation by way of now wings to existing hospitals, and possibly of separate hospitals for patients who would pay fees on a graduated scale. As foreshadowed in our last issue (p. 73), the committee strongly advises the introduction of a mutual insurance scheme to help persons of moderate means to meet the cost of maintenance and medical fees when in hospital. In general it recommends that the voluntary hospitals should make it a recognized part of their function to provide pay beds for the middle classes by means of fresh accommodation, and not using the beds now occupied by the working classes and the poor. For the well-to-do, who cannot obtain even in the most expensive nursing homes all the advantages of a fully equipped hospital, it is proposed that the hospitals should provide accommodation at charges which will show a clear profit, and thus provide a new source of revenue. By these various means, it is suggested, the voluntary hospital system would become a great co-operative effort for the benefit of all classes of the community.

THE GENERAL MEDICAL COUNCIL.

It would be well if the attention of the public and of the medical profession could be directed to an article in the July number of the *Empire Review* by Mr Norman O. King, Registrar to the General Medical Council, in which he expounds the composition, the duties, and the limitations of that Council. It is true that this task has previously been undertaken, and sometimes admirably performed, by various people on a number of occasions, even officially in the public addresses of the President of the Council, and in a "Memorandum as to the constitution, functions, and procedure" of the Council by the Registrar himself, published not long ago.² The present

article, however, in a popular review, is calculated to reach a different, possibly a wider, audience. It is, of course, authoritative, and remarkably clear and effective in spite of, or perhaps because of, its brevity. Mr King points out that the Council was not created to promote the welfare of professional men or professional corporations, or to put down quackery or to advance medical science, but simply, as the preamble of the Medical Act, 1858, says, "that persons requiring medical aid should be able to distinguish qualified from unqualified practitioners." The unqualified practitioner is left free in this country to practise for gain amongst those who choose to employ him, but he is forbidden, under penalty, to pretend that he is qualified. Qualified men, on the other hand, are subjected to the educational and disciplinary control of the Council. The Council consists of thirty-eight members, together with three dentists appointed for dental business only. Of these thirty-eight, only six are elected by members of the medical profession as a whole, and with regard to no fewer than twenty-three there is no obligation that they should even be members of the profession. The principal functions of the Council are three: first, to keep the *Medical Register*, secondly, to see that the name of no one is entered thereon unless his professional education has been adequate, or remains thereon when he has ceased to be entitled to public confidence, thirdly, to provide for the publication of the *British Pharmacopoeia*. The limitations of the power possessed by the Council in respect of both education and discipline are explained in the article, and the facts are emphasized that in considering charges made against practitioners the procedure of ordinary courts of law is followed as far as possible, that all the statutory powers are exercised for the protection of the public, and that there are special clauses in the Medical Act of 1858 which prevent the name of a practitioner being erased on the ground of his having adopted any special theory of medicine or surgery, and which prevent the licensing bodies from imposing on candidates any obligation to adopt, or refrain from adopting, any particular theory. These facts are well known to most members of the medical profession, but they seem to be but little understood by the public, and Mr King and the editor of the *Empire Review* have performed a very useful service by the publication of this article.

DAWSON WILLIAMS MEMORIAL.

FINAL LIST OF SUBSCRIBERS

SINCE the last list of subscribers to the Dawson Williams Memorial Fund was published in these pages cheques have been received from the following

Adams, Dr. H., and members of the Tyneside Branch of the British Medical Association
Anderson, Dr. G. C.
Baskin, Dr. J. Loughheed (Thame)
Canti, Dr. Ronald
Cunningham, Dr. W. (Whitley Bay)
Douglas, Dr. O. E. (St. Andrews)
Gabb, Dr. J. P. (Guildford)
Hall, Dr. Phyllis (North Shields)
Jones, Dr. Herbert (Bigbury-on-Sea)
Lord, Lieut.-Colonel J. R. (Epsom)
Leipoldt, Mr. O. L., F.R.C.S. (South Africa)
Martindale, Mr. W. Harrison Ph.D.
Martin, Dr. D. (North Shields)
Murray, Dr. J. (North Shields)
Nixon, Professor J. A. (Clifton)
Nixon, Dr. Doreen G. O. (Clifton)
Nelson, Dr. O. (Earsdon)
Rawson, Dr. N. R. (Whitley Bay)
Smith, Major General J. B., I.M.S. (ret.)
Sainsbury, Dr. H.
Towers, Dr. A. K. (Wallsend-on-Tyne)

The fund is now closed. The total number of subscribers is 400, and the total amount contributed is £885 14s. An account of the general meeting of subscribers held on July 10th was published in last week's *British Medical Journal* (p. 65).

AUSTRALIA AND NEW ZEALAND, AND OUR DUTY THERETO.

VICTOR BONNEY, M.S., M.D., B.Sc.,
F.R.C.S., F.C.S.A.

As the official delegate recently returned from the Annual Conference of the New Zealand Branch of the British Medical Association held last February in Hamilton, it was my privilege to present to the Council here a beautiful inkstand as a token of the loyalty and affection of the Branch for its parent body. Inscribed on the plinth are the words of Horace, "*Coolum non animum mutant qui trans mare currunt*," the sense of which has been happily paraphrased by Kipling in the lines

"They change their skies above them
But not their hearts that roam."

My journey to the antipodes, which officially took me through practically all the larger towns in New Zealand, and later, but not officially, into all the principal cities of Australia, and brought me into contact with a large proportion of the medical men in both countries, has given me an understanding of the deep meaning and beauty of the words of Horace obtainable in no other way. Loyalty and affection to a degree impossible to appreciate without such a visit sum up the attitude of the profession in these great Dominions towards the "Old Country," and this by men separated from the mother-soil sometimes by as much as three generations, and always by twelve thousand miles of sea.

Listening to the brotherly words of greeting that were showered on me as representing "Home," and noting the living interest taken in our work, our problems, and our difficulties, the question arose in my mind: Are we on our side doing all we can in return, and not trusting too much to the call of British blood, strong though it be? Our attitude, in fact, reminds me of that so commonly seen between brothers living a distance apart, between whom a strong affection subsists, though they see little of one another and correspond less. Each is occupied with his own business, each has his own circle of friends and acquaintances, and each treads his own furrow, feeling certain the while that in that undemonstrative affection lies the surety of aid in difficulty and misfortune. This is good enough between brothers, but is it good enough between cousins and second cousins and connexions still more remote? The answer is that, as far as families are concerned, it certainly is not. The basic affections and tendencies that characterize men and women of British stock are among the most unchangeable things in the world, but the pressure of geographical, economic, and racial environment is a great moulding force, which, left to act uncountered, may eventually produce wide differences in national outlook and national "culture." The antidote is closer contact and more intimate understanding, and in this matter the deficiency lies wholly on our side, for whilst, at a rough estimate, one out of every ten New Zealanders and Australians sooner or later visit the Old Country, one in a thousand would, I think, be a liberal estimate for the number of Englishmen and Scotsmen who visit the southern Dominions. The adage that seeing is believing is truest of all in its application to travel, and no amount of reading or hearsay can give that intimate vision which is essential if our duties to these great Dominions are to be grasped in full perspective.

New Zealand, which I visited first, is a country of beauties more varied than any other patch of land on the surface of the globe. Mountains throughout its length and breadth, it yet contains rich agricultural plains very much like England and the Scottish lowlands. Rolling, sheep-carrying uplands adjoin them, and from thence you

pass into high mountains which, in rock and glacier-type, more resemble Norway than Switzerland, though the peaks are of Alpine magnitude. From them, and from the great lakes that lie under them, rushing rivers proceed, which the angler at first glance perceives to be ideal salmon and trout waters, and the engineer vast potential sources of power. Across the North Island stretches the great thermal area with innumerable geysers, hot springs, and fumaroles, the medicinal value of which has only very partially been exploited. In the centre of it lies Lake Taupo, an inland fresh-water sea thirty miles long and broad, where anyone ambitious to catch a ton of trout can do so for a small licence fee. At its southern end stand three noble snow-covered volcanoes, one of them still active. One hundred and twenty miles south-westward is the extinct cone of Mount Egmont, which rivals Fuji in perfection of form, and sixty miles north-westward are the Waitomo caves lit up by millions of glow-worms, a unique and amazing sight. The vegetation covering both islands is rich and varied, the coast scenery everywhere beautiful, and the climate delightful.

The million and a half people of almost pure British stock who live in this gifted land have driven roads and railways throughout it and dotted it all over with well built modern towns and townships, of which the largest, Auckland, has close on 200,000 inhabitants, and it is in such surroundings that medical practice is carried on. At Dunedin, in the South Island, is the very up-to-date medical school which forms a part of the University of Otago, the standard of whose training will bear comparison with any other medical school in the world. The bulk of its graduates settle in the numerous towns as general practitioners, and, without making very large incomes, do well, for although the number of very rich people is small in New Zealand, yet, on the other hand, poverty is rare, and while certain articles are dearer there than here, yet on the whole the standard of luxury is lower, and there are less incentives and opportunities for spending money. General medical practice in New Zealand differs from that in England in that the distances from big centres are much greater, and the doctor has got to depend on himself to a much larger extent. Hence it comes about that nearly all general practitioners undertake not only minor, but major, surgery, and this is the more easily done because the Government has erected all over the islands small hospitals which, on the average, are much better equipped than the small hospitals here. In the larger towns there are finely equipped, big hospitals, also provided out of Government money, and certain of these are staffed, like our municipal infirmaries, by a paid superintendent and assistants under him, the local practitioners having no place in them, a bad system both for the profession and the community. The four capital cities possess big general hospitals with complete honorary staffs.

For those of us who cling to the voluntary system, the drawbacks of State maintenance are well exemplified, for not only is private charity almost non-existent where hospitals are concerned, but, being State supported, there is a strong body of lay opinion in favour of anybody and everybody being eligible as patients. This exploitation of the doctor is being strongly combated by the profession, but it is in the difficult position of one who, having got someone else to pay the piper, wants to call the tune. The easy route for obtaining medical ideals by getting the Government to pay for them is alluring to those impatient for such, but the price ultimately paid is the loss of autonomy and the selling of professional birthright.

Specialization is only possible in the capital cities, not merely because in these alone are there populations sufficient to maintain a specialist, but because to make a man an expert, and keep him an expert, a stream of cases sufficient in number from which to acquire and maintain

the necessary experience must be constantly forthcoming. In child welfare and district nursing New Zealand may be said to be one of the leaders of the world, and during the last year or two the question of how to reduce maternal mortality and morbidity has been receiving very serious attention.

The difficulties that confront the country practitioner in New Zealand in this matter are great, for not only is he himself isolated from professional assistance, but his patients frequently live at great distances from him, and to reach them he has often to motor twenty, thirty, or forty miles along bush tracks which we, accustomed to our good roads, would consider impassable by a car. Statistics in this and other countries clearly show that the risks of child bearing are greatest in districts where medical assistance is least easily available. To cope with these difficulties, to educate the public in the wisdom of placing women about to be confined in lying-in hospitals within easy reach of medical assistance, to encourage obstetrical research and to stimulate interest in all that pertains to the advancement of midwifery, and particularly to move the Government to create an obstetric professorship at the University of Otago, the Obstetrical Society of New Zealand has recently been formed. It has already done much useful work, and may confidently be expected to do much more in the future.

Australia is a land of such enormous distances that of its stupendous carpet I merely traversed a small part of the outer fringe. That part of the coastal zone that I saw is beautiful and of a pattern peculiar to itself. Ranges upon ranges of big hills covered with bluish green "bush" are interspersed with great grass and bush covered plains, shimmering under the brilliant sun. The impression is one of vastness, both of space and potentiality. The cities are large and beautifully spaced out, with every house standing in its own tree and flower-covered ground. Melbourne and Sydney hold between them over two millions of people, and, viewing them from within, you might imagine yourself in Liverpool or Manchester, rebuilt on a cleaner, finer scale. There are large medical schools in both of them, and also in Adelaide, staffed by men of the first rank and splendidly equipped, the department of anatomy and physiology at Melbourne, for instance, being by itself as large as any two London medical schools put together. The conditions of medical practice resemble those of New Zealand in some respects, and differ from them in others. Isolated from expert assistance as many New Zealand practitioners are, many of those in Australia are still more remote from it, and therefore have to equip themselves for, and undertake, every variety of work. Unlike New Zealand, however, the hospital system of Australia is largely voluntary, the Government merely supplementing the efforts of charitable subscribers, and the medical profession therefore is free of those handicaps which beset its brethren in the smaller Dominion.

The principal cities of Australia being as large as ours (London excepted), specialism obtains in them to the same extent that it does with us, and the average calibre of the men who staff the big hospitals and teach in the medical schools is also equal to ours. In both countries, but in New Zealand in particular, it is usual for the best of the younger men, after qualifying and holding house appointments, to spend a year or more in Great Britain and the Continent for the purpose of post-graduate study and the holding of house appointments in England, and a considerable proportion of them take the Fellowship of the English or Scottish College of Surgeons. As is well known, the average standard of those who take house appointments here is very high.

As regards surgery, Australia and New Zealand are in somewhat of a transitional state. In a new country, whose population is sparsely spread over great areas its medical

men have to undertake every sort of work, for specialists are few and not as a rule available by reason of the distances. As the population increases and large cities and better means of communication arise, the necessity for men in general practice to undertake major surgery becomes less and less, until at last the ideal stage is reached in which every person requiring an operation can, without difficulty or delay, be operated upon by a fully trained surgical specialist. Between the first and last stages lies an intermediate one in which both the general practitioner-surgeon and the surgical specialist have a place, and at which point this intermediate stage should pass into the last or ideal stage is a matter on which opinions differ. In order to produce a fully trained surgical specialist a large amount of clinical material, allocated to him alone, is required, and it is obvious, therefore, that the number of such men capable of being turned out year by year in any given country depends on the size of the population, assuming, of course, that the total clinical material is used to the full. In the intermediate stage, therefore, it becomes a question whether it is better for the community to have a large number of lesser-trained mediocre surgeons or a smaller number of fully trained first-class surgeons. It is for the purpose of regulating the growth of surgery and cultivating and maintaining the highest principles of surgical practice and ethics that the College of Surgeons of Australasia, which includes New Zealand, has been formed, and its inaugural meeting, which was opened by the Governor General, Lord Stoneham, at Canberra last March, marked an important step forwards.

I have thus briefly reviewed the medical profession in the two Dominions, and the conditions and circumstances under which it trains and works, in order that those of us over here, who perhaps have not given the matter much thought, may realize the importance of maintaining to the full, and increasing if possible, the spiritual alliance which binds them to us. Medicine, like the body, is both spiritual and material. In so far as it is material it is cosmopolitan, for there is no difference in its technique throughout the world. On the spiritual side, however, there are wide differences depending on national outlook, national circumstances, and national character, and the spirit of practice is far more important than the method of practice.

Australia and New Zealand are an enormous distance from Great Britain, and unless we are prepared to overcome that disadvantage by more deliberate efforts than have yet been made, there is a possibility that the pressure of their more immediate environment may cause their spiritual outlook to become in time deviated from ours. The United States of America are comparatively near neighbours to them, and of recent years there has become apparent in certain quarters a tendency to look to that great country for material help and spiritual guidance. The American outlook necessarily differs from the British outlook, and whether one is better than the other is a matter of opinion, but there can be no doubt as to the desirability of British nations being guided by British ideals. A tour such as I have made leaves one with the impression that in this matter Great Britain is singularly supine. For one Englishman who visits the Dominions twenty Americans go, and of every twenty motor cars in Australasia nineteen are American, whilst, coming down to our own profession, all the radiological plant and most of the medical books, operating tables, and instruments are American, and this among peoples who ardently desire closer community with us. The necessity for a revision of our methods appears to me to be urgent, and as far as our own profession is concerned, two things are quite clearly called for: first, an improvement in the facilities open to Australians and New Zealanders for post-graduate work in this country, and secondly, personal visits to the Dominions by representatives of the profession at

homo to promote better understanding and more intimate relations

The need to improve our post-graduate facilities is very great. Much admirable work has already been done by the Fellowship of Medicine, but we are still far behind. In the American and Continental clinics all the post-graduate work is under one roof, and classes, demonstrations, and courses in special work are without difficulty and without delay at the service of those seeking them. The graduate from abroad is deliberately catered for by well-organized arrangement, and, more than that, he is received with open arms as a visitor much to be desired, and all manners of kindness and hospitality are showered on him. London, with its widely spread hospitals and its multiplicity of staffs, is admittedly a knotty problem from the point of view of post-graduate education, and the more so because all the larger hospitals have their own medical schools, and it is difficult to organize post-graduate clinics without interfering with the education of the students. The primo requirement is a large hospital devoted solely to post-graduate work, but pending this a great deal more could be done by concerted effort if only the urgent need of such effort, not merely for professional but for national reasons, was grasped by all concerned.

Finally, I want to press the importance of personal visits, not for the sake of what the best of us can teach these brethren of ours, if it be anything at all, but for the sake of the gesture that the visit implies. Many of us visit America and the Continent, but those great lands wherein lies the ultimate hope of our race have first claim on us, and he who journeys out to them in interest and good fellowship puts another rivet in the great chain, and is an ambassador needing no other credentials for his welcome than that he comes from "Home."

ROYAL SANITARY INSTITUTE

THIRTY-NINTH CONGRESS

THE thirty-ninth Congress of the Royal Sanitary Institute opened at Plymouth on July 16th, under the presidency of Viscount Astor. Its work, which continued throughout the week, has been conducted in seven sections, dealing with various aspects of hygiene and sanitation, and in seven conferences of groups of workers and representatives of authorities. Lord Astor, in his address, contented himself with what he described as a superficial review of modern developments in preventive medicine and hygiene, and pointed some contrasts between present and former times. He declared that fewer lives were lost by plagues, including small-pox, in a year than were lost through accident on a fine Bank holiday.

The Tuberculosis Problem

In the Section of Preventive Medicine, over which Dr L. RAJCHMAN, medical director and secretary of the Health Committee of the League of Nations, presided, a discussion on the present position of the tuberculosis problem was opened by Dr F. J. H. COURTS of the Ministry of Health. The factors which had brought about the decline in mortality from tuberculosis, he said, were certainly not due solely to special measures taken against the disease. Nor could he agree that mysterious cosmic forces over which we had little or no control were concerned. The progress of sanitary reform and social well-being greater appreciation of the value of fresh air, sunlight, and exercise, as well as special measures for prevention and treatment, had all played a part. He pointed out, however, that the recent figures showed that the age period 15 to 25 had failed to share in the general reduction of mortality, and that female mortality at this period had actually increased of late years. Dr ERNST WIND (tuberculosis officer, Devon County Council) said that the best line of attack was preventive measures, and, above all, avoidance of infection. If public health officers collaborated on the lines with each other and with the general practitioner,

tuberculosis should become a rare disease within two generations. Dr LEONARD KEITH (M.O.H., Bethnal Green) spoke on tuberculosis as a family and economic problem, and advocated subsidized employment schemes. In another section Dr W. G. SAVAGE (M.O.H., Somerset) criticized the working of the Tuberculosis Order, 1925, from the point of view of milk infection. He said that the cattle were for the most part only notified and slaughtered in the late stages of the disease, when they had already been infective for long periods.

Rheumatism

In the Maternity and Child Welfare Section Dr R. C. LIGHTWOOD (Kensington) discussed the question of juvenile rheumatism from the point of view of public health administration. He said that voluntary hospitals—especially the children's hospitals—were seeing the gradual disappearance of groups of cases as they came under the organization of various State and municipal schemes, such as tuberculosis and venereal diseases centres and school clinics. This had obvious disadvantages, the remedy for which was to keep such centres and clinics in close association with hospitals. He urged that rheumatism supervisory centres should be, as was the case in Kensington, under consulting physicians who were attached to the hospitals, so as to ensure unity of control. He disagreed with the term "cardiac centres," holding that the idea of the prevention of juvenile rheumatism should be in the forefront. No scheme was complete without adequate provision of convalescent accommodation; public money might be wisely spent in providing hospital schools. Dr MARGARET DASHLE said that in the rear of the acute alarms of the rheumatic condition lurked a state of ill health and cachexia, in itself very possibly not specific until a specific infection was grafted on to it, and in this background vitamin deficiency was very likely to be an important factor. Dr FLORA SHEPHERD (Hornsey) protested that the classical teaching that rheumatism was a disease non-existent in infancy and very rare in pre-school age had prevented its recognition at a time when this would have been most valuable. Dr A. P. CWARDIAS advocated the claims of spa treatment even for the slighter forms of rheumatism, and urged that children belonging to families in which chronic rheumatism prevailed should be sent to spas. In another section the relation of rheumatic heart disease to industry was discussed. Dr CAREY F. COOMBS (Bristol) pleading for more careful consideration of the possible organization of suitable employment for persons with advanced cardiac disease, while the value of the factory clinic in dealing with industrial invalidity, one-sixth of which was said to be due to the "rheumatic" group of complaints, was emphasized by Dr L. P. LOCKHART (Nottingham).

Immunity Methods in Scarlet Fever and Measles

The Section of Preventive Medicine also discussed immunity methods in scarlet fever and measles. Dr W. A. LETHBRIDGE (Ministry of Health) suggested a scheme for the general use of convalescent measles serum, which, he said, had proved to be an effective weapon of defence. It was worth while for medical officers of health and public authorities to go to some trouble and expense to provide this protection in time of need. Dr W. T. BENSON (Edinburgh) said that in scarlet fever the Dick test and the subsequent active immunization of susceptible individuals was worthy of more general application, while in certain limited fields, more particularly in hospitals or institutions for children, the method of sero-prophylaxis or sero-attenuation of measles was also of undoubted value. The limited source of supply of the immunizing serum, however, practically invalidated the general application of the method to the child population. Dr J. P. KINLOCH (Aberdeen) considered that the available scarlatinal toxins could be used with advantage for purposes of community immunization. Even though complete immunity might not be achieved in all individuals taken, nevertheless the primary stimulus would have the effect of making the patient's immunity mechanism respond with greater strength when sub-infectious—or even infectious—doses of

streptococci were received. With regard to measles, certain work in Aberdeen indicated that, apart from the promising but limited field within which convalescent serum might be used for inducing a passive immunity, the prophylaxis of measles on a comprehensive scale awaited the confirmation of the findings of Degkwitz (1927), whose extensive researches the speaker summarized. Dr L. H. R. HARRIES (Birmingham) added a note on the serum prophylaxis of measles with special reference to two horse antiserums, as to which his verdict on the results was "not proven", and Dr R. A. O. BRIEF (Wellcome Research Laboratories), in another paper, claimed that it could fairly be said that the basis of a sound means of prevention, diagnosis, and treatment of scarlet fever had been laid. As for measles, the utility of convalescent serum for conferring either temporary blood protection or for giving active lasting immunity, dependent on the time of giving, was accepted. The problem for public health authorities was to provide and maintain a supply of serum by appeals for volunteers.

National Health Insurance

A discussion on this subject was to be opened yesterday (Friday) by Mr. HENRY LEFFLER (president of the National Association of Insurance Committees), an advance copy of whose remarks shows that his general line of argument was that the State insurance system contained within itself elements of a much larger growth than was apparent to-day. He demurred to the title "national". It was not a national service to enter insurance; a man or woman must first be employed; individuals were brought within the scheme, not as citizens but as wage earners. It was this industrial character of the scheme which distinguished national health insurance from other public health services. Industry, it would appear, was bearing more than its fair share of the cost. Parliament might not unreasonably have increased the State grant, but decided instead, under the Economiser Act, 1926 to reduce it. It might be true that in times of national stringency the nation must turn from "searching its conscience to exploring its purse," but with the growth of democratic institutions human values could not for long be underestimated without danger to society. Mr. W. M. MURRAY (Scottish Association of Insurance Committees) held that sooner or later the Government must provide, where necessary, specialist and consultant treatment, and must face the difficult and perplexing problem of hospital accommodation. The approved societies must answer the growing demand that in respect to treatment benefits all insured must share alike, and the medical profession would require to realize "in a much greater degree that the granting of public moneys and the assumption of public service carry obligations which involve restraint and discipline on those of their number who are impatient or careless." Mr. STANLEY L. DUFF gave an account of the development of approved societies, and cited some figures relating to additional benefits, from which it appeared that dental benefit covered approximately 12,700,000 persons and involved appropriations of £2,642,402, and ophthalmic benefit 11,900,000 persons and appropriations of £421,199. A further paper was by Mr. GILL HOBSON (clerk to the Liverpool Insurance Committee), who said that there appeared small likelihood of an extension to dependants being made for some time. In his judgement the present service should be made efficient and complete before any further classes of persons were brought into the scheme. Mr. E. F. SPRUNGEON (Prudential) spoke of the seriousness of the present high level of sickness experience. It was possible that the experience might be lightened by improvement in industrial conditions, but the progress of claims on the fund from year to year was not encouraging, and there was need for constant watchfulness on the part of approved society officials, for strict conscientiousness in the granting or withholding of certificates by practitioners, and for cordial co-operation between approved society officials and the medical profession. Resolutions were before the conference favouring the extension of the scope of medical benefit and urging the immediate provision of expert medical advice and treatment—alike for people able and unable to travel to meet the specialist—and laboratory services, and also (in the name of Dr. F. G.

Bushnell) urging that the Ministry of Health be asked to make provision to enable insurance committees to promote or assist local anti-cancer centres on approved lines.

Among other communications presented to the Congress were a number of papers on light treatment and the experience of municipal authorities in its provision, several on recent advances in research on puerperal fever, and a number of papers dealing with the less directly medical side of the Institute's activities, of interest more particularly to sanitary inspectors, health visitors, and veterinarians.

BEIT MEMORIAL FELLOWSHIPS

At the twentieth annual meeting of the trustees of the Beit Memorial Fellowships for Medical Research, the appointment as trustees was recorded of Mr. W. Ormsby Gore, M.P., and Lord Onslow, in the place of the late Sir Arthur Shrapley and the late Lord Cave.

In his annual report the honorary secretary, Sir James K. Fowler, M.D., said that the Advisory Board was able to record that the high standard previously reached by candidates for election to fellowships had been maintained. Moreover, reports from the directors of laboratories showed that, as in previous years, the Beit Fellows had been actuated in their work by the true spirit of research and were endeavouring to carry out the primary object of the Trust—"the advancement by research of medicine and of the sciences allied therewith." The extreme subdivision of these sciences had now made it very difficult to present in a manner intelligible to those not engaged in such studies a summary of the advances in knowledge made during the past year by the Fellows, owing to the wide field covered by their researches. To this general statement, however, one exception might be made—that of Dr. Edward Hindle on yellow fever—a disease to which unusual attention had lately been drawn by the lamented deaths of Adrian Stokes, Hideyo Noguchi, and William Alexander Young, while engaged in its study on the West Coast of Africa. Dr. Hindle, who was appointed last year to the newly established Beit Fellowship in Tropical Medicine, began work in January, 1928, and in the short period that had elapsed since then had obtained results in the course of a research on yellow fever which gave good ground for the belief that a vaccine had been discovered which would afford protection against that disease. It had been long known that the causative agent was carried from patient to patient by *Stegomyia fasciata*, a mosquito with many aliases. To Adrian Stokes and his fellow workers at Lagos the credit was due of having shown that by mosquito infection the disease could be transferred from man to the Asiatic monkey *Macacus rhesus*. African monkeys, on the other hand, were known to be immune. Dr. Hindle and Dr. A. W. Sellards (*British Medical Journal*, April 28th, p. 713) proved that the virus would bear carriage by sea in a refrigerator for twelve days or more and still maintain its virulence, and that it belonged to the group of filterable viruses. Dr. Hindle, working independently, had since shown (*British Medical Journal*, June 9th, 1928, p. 976)—

- (1) That the virus could be preserved when present in a portion of liver or of the blood of a monkey dead from the disease by drying it in a vacuum and that as a dried paste or as a powder it retained its virulence apparently for an indefinite period.
- (2) That if an animal were admitted to the containing vessel the virus was still active after a period of certainly three weeks or a month.
- (3) That a very minute dose of the virus was invariably fatal in from four to seven days to monkeys of the species *Macacus rhesus*.
- (4) That a vaccine prepared from the livers of infected monkeys would protect a monkey from the effects of a dose of the virus ten thousand times as great as the fatal dose and the monkey continued to be healthy and lively.

There are many points [the report continues] still to be decided during the further course of Dr. Hindle's research, such as (a) the best methods of preparing and of administering the vaccine, (b) the dose necessary to afford protection, (c) how long does the protection last? (d) will the vaccine keep? (e) the best form in which to transport it to the countries where it is wanted, (f) are the results obtained with monkeys also true of man? Dr. Hindle's research at every stage in the process of manufacture and testing of such a vaccine will require the closest possible supervision by men skilled in laboratory technique. It may prove advisable that it should be made in a country free from yellow fever and from the presence of the mosquito (*Stegomyia fasciata*) certainly capable of acting as

a carrier. The benefit conferred by this discovery, assuming its value to be ultimately established, will not be limited to Europeans living in a country where the disease is endemic or in which it appears at intervals. It will be shared by the native population, who are not immune, as some, in spite of what should be convincing evidence to the contrary, still appear to believe.

The following were elected to Beit Research Fellowships

Senior Fellowships (value £700 per annum), fourth year Fellows elected to Senior Fellows—(1) Alan Sterling Parkes, subject 'The proportion of the sexes' (2) Miss Honor Bridget Bell, subject 'Experimental studies on the differentiation and dedifferentiation of animal tissues'

Junior Fellowships (value £400 per annum)—(1) Juda Hirsch Quastel, D.Sc., Ph.D., (2) Percival Walter Clutterbuck, M.Sc., Ph.D., (3) Bryan Harold Cabot Matthews, B.A., (4) Douglas Roy McCullagh, M.Sc., (5) Wallace Ruddell Aykroyd, M.D.

England and Wales.

Centenary of the Sheffield Medical School

The centenary of the Sheffield Medical School was celebrated on July 11th by a special degree congregation, over which the Marquess of Crewe, Chancellor of the University, presided, in the presence of a large assembly of members of the University and of the public in the Fifth Hall. Lord Crewe expressed the regret of the University at the loss by death of Dr. Dyson, late professor of medicine, and after welcoming the delegates from other universities he said that the growth of the medical school and its development into the medical faculty of the University was a singular case of one limb of a great organism being more than four times as old as the organism itself, and yet not, in any sense, the parent of the organism. The medical faculty, he continued, was, in fact, an integral part of the University, it was an advantage to the school of medicine to have become a department of the University, and no less an advantage to the University to possess so distinguished a medical faculty. The representatives of other universities were then presented to the chancellor and tendered congratulatory addresses. Sir E. Farquhar Buzzard, Regius Professor of Medicine, Oxford, referred to the somewhat turbulent beginnings of the Sheffield school, largely due, he said, to the methods—necessarily secretive and sometimes unseemly—at which the profession was in those days forced to connive for the sake of promoting the study of human anatomy. In recent years, he added, the contributions of the Sheffield school to the advancement of medical knowledge had been numerous and valuable, and the names of its professors and teachers had become familiar to the profession throughout the world. The record of the school was one to be proud of, as an earnest of even greater achievements in the future. Sir Humphry Rolleston, Regius Professor of Physics at Cambridge, said that one hundred years ago medical matters were in a state of turbulence, the Cambridge medical school was in low water and came near to being abolished about the time when the Sheffield school was born. Both schools could now look back with gratitude to the determined men who had made their present position possible. Sir Humphry recalled the fact that the first regius professor of physics at Cambridge, who was appointed in 1540 was John Blythe, a native of Sheffield. He then paid a very high tribute to Professor Arthur Hall, who for forty years had served the Sheffield Medical School and the University as teacher and administrator in many capacities. The honorary degree of doctor of science was then conferred by the Chancellor on Dr. H. Hallett Dale, Professor Arthur J. Hall, Sir Frederick Gowland Hopkins, and Sir Thomas Lewis. Professor Hall, as was to be expected, was received with enthusiasm, being known personally to every member of the audience, not only as a distinguished physician, but also for his outstanding services to the University—in the creation of which he played a leading part—in, successively, the chairs of physiology, pathology, and medicine, and, latterly, as dean of the medical faculty. After the congregation the representatives of the city, of Sheffield University, and of other universities were enter-

tained at an official luncheon by the faculty of medicine, and in the evening a large party attended a *conversazione* at the University.

Welsh Board of Health

The Minister of Health, on July 11th, received a deputation of Welsh members of Parliament, who waited upon him to discuss certain recent changes in the Welsh Board of Health, notably his decision not to appoint a successor to Sir Thomas Hughes, who was until recently chairman of the Board. Mr. Lloyd George said that there was a very strong feeling throughout the whole of Wales regarding the matter, and went on to refer to the effect of the changes in relation to national health insurance administration, saying that he had been under the impression that Wales was in the same position as England, Scotland, and Ireland in respect of the autonomous administration of its affairs under the Insurance Act. The Minister's decision, he suggested, had the effect of drawing a distinction between Wales and the three other countries, and the deputation felt that this was a detriment to the Principality. This feeling of indignation was shared by members of all parties in Wales. Mr. L. Lougher and Mr. Will John supported this view. Mr. Nevill Chamberlain replied in terms similar to those he employed in explaining the change in answer to questions in the House of Commons, as reported in our Parliamentary Notes on July 7th (p. 38). The view that the recent changes affecting the Board would diminish its powers was, he said, an entire misapprehension. He had in his mind no policy the effect of which would be gradually to diminish the powers of, and possibly ultimately to abolish, the Welsh Board of Health. The steps objected to had been taken solely in the interests of good administration. Wales had never been in the same position as Scotland or Ireland. The Board was not an executive board in the ordinary sense of the term, its work was, in fact, done by its individual members in their separate individual capacities. He had considered the question and had come to the conclusion that, for one reason or another, none of the existing members of the Board could be regarded as suitable for the post of chairman, he had considered whether he should appoint some person who was not now a member of the Board, but such a man could not be found without causing inconvenience elsewhere, and, moreover, it would have involved expense which did not seem to him to be justified. He had therefore decided to make no appointment. The deputation indicated that in view of the Minister's statement they would like to discuss the matter further themselves, and would then, if necessary, approach the Minister again. Mr. Chamberlain said that he did not feel that any of the representations made would justify him altering his decision, but he would be pleased to consider any further points the deputation might raise.

University College, Nottingham. Opening of the New Buildings.

On July 10th the King and Queen opened the new buildings of University College, Nottingham, of which an account appeared in our issue of July 7th (p. 20). Popular enthusiasm was heightened by the announcement made by the King on reaching the city boundary that, in consideration of the antiquity and importance of Nottingham, the chief magistrate should in future be entitled "Lord Mayor." The King was received at the east end of the college quadrangle by the Duke of Portland, who is president of the Court of Governors, and Alderman Huntsman, Lord Mayor of Nottingham, who is chairman of the College Council. They were accompanied by the President of the Board of Education, and a guard of honour of the University College Training Corps was mounted in the East Court, where also was the band of the Sherwood Foresters. Their Majesties were then conducted to the main doorway in the quadrangle, above which is the inscription *Ad gloriam Dei et homines artibus instruendos has aedes curavit aedificandas Iesse Boot Baronettus MCMXXIII*. Here several presentations were made, including Lady Boot, Professor W. H. Heaton, Principal of the University College, Dr. Frank Granger, Vice-Principal, and Mr. Morley Horder, the architect. The King then opened the

main doorway with a gold key, passing through the new buildings into the great hall, where a prayer of dedication was said by the Vicar of St Mary's. The chairman of the College Council read an address in which the history of the institution was traced from the year 1877, when it was established as a direct result of the Cambridge University Extension Movement. Reference was made to the Royal Charter granted in 1903, and to the rapid progress since that date. The part played by Sir Jesse Boot since 1921, in enabling the institution to accord the increased facilities for instruction which were urgently demanded, was then detailed, and mention was made of the hall of residence for some eighty women students, which Lady Boot had presented and which was nearing completion. Grants had also been received towards the assistance of students in poor circumstances. The chairman mentioned that, as the result of a public appeal, over £130,000 had already been received as the beginning of an endowment fund, and the hope was expressed that at no distant date Nottingham would be able to take its place among the fully chartered universities of the country. In reply to the address the King voiced his especial pleasure in opening the new buildings, and congratulated those concerned on the support that had been received from all classes of the population of the city. He added that in the prevailing conditions no nation could afford to withhold from its citizens the fullest measure of training and culture. The college was in a very real sense the child of the corporation, under the watchful and generous care of which it had thriven, so that it was now able to establish itself outside the city in magnificent buildings and grounds, with ample lecture rooms, laboratories, library accommodation, and extensive playing fields. The King referred particularly to Lady Boot's generous gift of the new hall of residence for women students. Their Majesties then proceeded to inspect the new buildings, including the lower hall, the library, the refectory, and the terrace, subsequently taking tea with Sir Jesse and Lady Boot.

Presentation to Dr D S Davies

On his retirement from the post of medical officer of health for Bristol, after over forty years' service, Dr D S Davies was presented by his numerous friends and colleagues with a portable wireless set and a cheque. The ceremony was provided over by Dr Kenneth Wills, president of the Bristol Medico-Chirurgical Society, in the unavoidable absence of Professor Hey Groves, president of the Bath and Bristol Branch of the British Medical Association. The chairman voiced the regret felt at the retirement of Dr Davies, and wished him long life, health, and happiness. Dr Wills alluded to previous positions held by Dr Davies, including those of president of the Bath and Bristol Branch of the British Medical Association, of the Bristol Medico-Chirurgical Society, and of the Society of Medical Officers of Health. Dr Davies has also been a member of Lord Trevethin's Commission on Venereal Diseases in 1922, and an examiner in State medicine for London University, and for the diploma of public health examinations in connexion with the Conjoint Board and the Universities of Bristol, Cardiff, and Belfast. He received the honorary degree of LL.D. from Bristol University in 1912.

The Cicely Northcote Trust

The admirable service rendered to St Thomas's Hospital by the Northcote Trust is made the subject of a foreword to the present report by Mr G Q Roberts, the hospital's secretary. The activities of the Northcote Trust are already widely known. It was established in 1909 by Mr Hugh Northcote, and one of the conditions of the trust was that the same measure of assistance already being given to the out-patients of the hospital should be available for the in-patients and their families. In 1904 the governors of St Thomas's appointed a lady inquiry officer to be known as the lady almoner. This appointment foreshadowed a very wonderful development of the hospital work, and led to the establishment of a staff of lady almoners, whose duties, however, were confined until 1909 solely to the investigation and relief of the social conditions of the very many out-patients in attendance. The medical staff quickly

realized the great value of this assistance, and heartily welcomed the extension of the scheme to the in-patients and their families, as was made possible by the generosity of the Northcote trustees. Many instances are given in the present report to show the very great benefit afforded to the in-patients as a result of inquiry and help by the lady almoners, and it may now be said that there are few patients in the hospital whose circumstances are not sufficiently well known to obviate any possibility of hardship to them or to their families through neglect. Medical practitioners are well aware of the difficulty often encountered of inducing many patients, especially mothers, to come to hospital in the early stage of an ailment, as, for example, an incipient cancer. A wife, perhaps, says she cannot leave her home. Who is to look after her children? It is just here also that the services of the lady almoners' staff are so valuable. Arrangements are made with an employer to keep a situation open, or with someone to take the place of the worker at home, to carry on during the patient's stay in hospital. The most delicate and difficult duties of the lady almoners' staff, however, are concerned with the help and rehabilitation of patients suffering from mental ailments. In any large general hospital there are always to be found a number of patients who suffer from neuroses or from more serious mental disorder. It is not surprising that in cases where home conditions are particularly trying and disagreeable such patients should look on the hospital as a quiet haven from the struggle of life outside, and find it extremely difficult to return to their hard daily routine. In many cases it is the task of the lady almoners to find fresh environment, new purposes, and interests which may open fresh avenues to a normal healthy life. The report refers to the need for full and adequate treatment in the early stages of mental disorder, and to the fact that the task confronting the Northcote Trust worker in these cases would be far less complicated if patients came for treatment before they had taxed to the utmost the resources and understanding of their family and friends. One of the chief difficulties in dealing with the re-establishment in the outside world of patients with long histories of neuroses is the inadequacy of the information as to their previous admissions to hospitals or clinics, and it is urged that some machinery for passing on the histories from treatment centres be evolved. It is only by such means that the hospital after-care worker can hope to achieve her object.

Scotland.

Small-pox in Scotland

THE outbreak of small-pox mentioned in the *Journal* of July 14th (p 72) is attracting considerable attention from local authorities in Scotland. In Brechin investigation of cases notified as chicken pox has resulted in the discovery that a certain number are in fact small-pox, similar to the type of which there were some 150 cases in Dundee last year. In Glasgow a warning has been issued by the medical officer of health advising Glasgow people who may be arranging to spend a holiday in the district where small-pox has broken out to be vaccinated before going there.

Harvey and Aberdeen

At the June meeting of the Aberdeen Medico-Chirurgical Society, with Dr Thomas Fraser in the chair, Professor J A MacWilliam, FRS, gave an address entitled "Reflections on Harvey's work." After some remarks on the life and personality of Harvey, he sketched the long-established views associated with the name of Galen, and the contributions of some of the precursors of Harvey—Servetus, Leonardo da Vinci, Fabricius, and others. The fundamental observations and animal experiments were reviewed, and also the reasoning which led Harvey to the idea of "a movement, as it were, in a circle," together with the work of the successors of Harvey (Malpighi, Leeuwenhoek, and others) in demonstrating the capillary circulation. The profound significance of Harvey's great achievement was emphasised, not only in its obvious applications of fundamental importance in physiology and

medicine, but also as regards the change which it had induced in the general attitude of mind towards the problems of the animal organism, introducing a new spirit and method in the study of the relation to the forces and processes of the external world. Dr W. Clark Souter read a paper on the visit to Aberdeen in 1641 of William Harvey, when he was made an honorary burgess of the city. Dr Souter showed a number of lantern slides illustrating this and other Harveyian topics, together with a number of Harvey portraits, he gave his views on the authenticity and origin of the Harvey portrait in the society's possession, a gift from Sir Walter Traquair in 1815.

Tuberculosis in Aberdeenshire

The annual report of Dr H. J. Rao, medical officer of health for Aberdeenshire, dealing with the year 1927, is specially concerned with the question of tuberculosis. It is stated that, in this country, institutional treatment is provided on a most generous scale, and patients after treatment in an institution are offered the use of shelters which can be erected in rural areas and other places where open space is available. While it is agreed that efforts at eradicating tuberculosis have met with a considerable measure of success, which institutional treatment has undoubtedly helped, it is suggested that institutional treatment can never eradicate tuberculosis, for, although an expensive therapeutical method, it occupies a relatively short period in the patient's life. Tuberculosis is a social problem intimately related to heredity, wage-earning capacity, and social and housing conditions, and it is really a disease of the home. Institutional treatment, however, teaches the patient how to live and regain some degree of working capacity as well as how to avoid a recrudescence of the disease.

Edinburgh Post-graduate Courses

The syllabus of post-graduate courses for the approaching vacation term has been issued by the committee appointed by the University and School of Medicine of the Royal Colleges to arrange them. These courses have now been given since 1906, except for the period of interruption during the war. The syllabus announces courses in tuberculosis, venereal diseases, surgical pathology, diseases of the nose, ear, and throat, and ophthalmoscopy, to be held at various times of the year at fees ranging from two to ten guineas. The special vacation courses now commencing include the following: A course in obstetrics, gynaecology, and diseases of children will be held from July 16th to August 11th, and includes daily clinics at the Royal Maternity Hospital and in the gynaecological wards at the Royal Infirmary, attendance at child welfare clinics, ante-natal clinics, and clinics on diseases of children in the Royal Hospital for Sick Children, and a series of lectures upon such subjects as infant feeding and ophthalmia neonatorum, the fee for this course is ten guineas. A general practitioners' course will commence on August 13th and continue for four weeks till September 8th, it will include demonstrations upon applied anatomy, but will be mainly clinical, with meetings in the Royal Infirmary for clinical medicine and clinical surgery daily, clinics twice weekly in the Royal Hospital for Sick Children and special clinics once weekly upon infectious diseases, gynaecology, diseases of the eye, diseases of the throat, and dermatology, in the afternoons demonstrations will be arranged with reference to bacteriological diagnosis, morbid anatomy, lupus, radiology, ultra violet light treatment, dental treatment, and venereal diseases, the fee for this course is ten guineas. A general surgical course runs concurrently with the last and includes demonstrations in applied anatomy, the surgical diagnosis of renal disease, abdominal surgery, orthopaedics, and surgical pathology, there are also clinics relating to general surgery, surgical out-patients, gynaecology, surgical diseases of children, venereal diseases, and radiology, the fee for this course is ten guineas. Various special courses at individual fees can be taken at the same time if desired in such subjects as vaccine therapy, medical chemistry, and diseases of the blood. Application to join any of the courses should be made to the Secretary, Post-graduate Courses in Medicine, University New Buildings, Edinburgh.

Correspondence.

CARBOHYDRATE METABOLISM IN HYPERTHYROIDISM

SIR,—Dr Henry Moll has recorded in your issue of July 14th (p. 51) the beneficial effects of a diet rich in carbohydrates in cases of Graves's disease. These clinical observations confirm the conclusions, arrived at by me ten years ago as the result of observations in experimental hypothyroidism in animals, that "in Graves's disease a carbohydrate-rich diet is indicated to counteract the loss of flesh which is one of the features of the disease." Since most writers on the relation of the thyroid gland to carbohydrate metabolism find it difficult to correlate the known facts, this may be a suitable opportunity to give a brief re-statement of a conception which I have put forward in a number of papers, and which, so far as I can see, affords an adequate explanation of the various apparently paradoxical features of hyperthyroidism.

In hypothyroidism, however induced, there is a stimulation of the glycogenic functions of the liver in the sense that more sugar is being passed into the blood and more glycogen is being formed by the liver. The sugar which is passed into the blood is oxidized away so that the blood sugar shows no marked deviations from the normal. As the result of the increased formation of glycogen the liver begins to attack the protein of the body and transforms it into glycogen. Hence the increased nitrogen excretion and the loss of weight. It is logical, therefore, to counteract this effect by increasing the available carbohydrate in the diet.

This statement refers to the simple uncomplicated conditions of hypothyroidism in which there is never a glycosuria. But hyperthyroidism, if prolonged, may be complicated by secondary changes which manifest themselves clinically by more severe disturbances in the blood sugar or even by the development of diabetes mellitus.

Experimentally Burn and Marks have recorded the paradoxical behaviour of the blood sugar occurring in rabbits which had been kept in a condition of hyperthyroidism for several weeks. Prolonged thyroid feeding produces changes in the suprarenal glands which I have interpreted as an inhibition of the gland, and I suggested that Graves's disease may be due to a breaking down of this inhibiting mechanism in the suprarenal gland. It also produces definite changes in the islets of the pancreas, the significance of which is yet obscure. In pathological hyperthyroidism, as it occurs sometimes spontaneously in mice, I have recently been able to observe definite changes in the suprarenals of four such cases. These mice, which were put at my disposal through the kindness of Professor L. Hill, showed a very pronounced exophthalmos and had greatly enlarged thyroid glands. In three the suprarenal medulla was greatly hypertrophied and was actively secreting. In the fourth animal the medulla of one suprarenal was greatly hypertrophied while the medulla of the other gland was almost completely atrophied.

The observations indicate that in pathological hyperthyroidism the suprarenal gland is frequently, if not always, involved, but that the extent to which it is involved differs greatly in different cases. At first there is stimulation, but, as the one case referred to shows, this may be followed by degenerative changes. The condition of the carbohydrate metabolism will vary accordingly. With a hyporeactive suprarenal the glycogenic function will be stimulated, when the gland degenerates it will be inhibited. In pathological hyperthyroidism, in which there is always a prolonged activity of the thyroid gland, the metabolic condition cannot be explained entirely by reference to the state of the thyroid gland. The state of the suprarenals, and probably also of the islets of Langerhans, have to be considered. A more detailed statement will be found in my recently published book, *Fever, Heat Regulation, Climate and the Thyroid Adrenal Apparatus* (Longmans, Green and Co.)—I am, etc.,

London WC1 July 16th.

W. CRAMER

A CAROTID RESPIRATORY REFLEX

SIR—In your interesting annotation on the work of Danilopolu and his collaborators at Bucarest, under the above heading in the *Journal* of July 7th (p. 25) you state that "the reflex is started in the tunica intima of the artery, and at a particular spot in the carotid sinus." Further on "So far very little study has been undertaken of the relation of the reflex to pathological conditions." If this observation is correct—that the reflex is started in the tunica intima—it may be of great importance, especially in its relationship to the causation of sudden death.

In an investigation¹ of 100 cases of sudden death under anaesthesia and unexplained deaths in circumstances which called for examination by the Crown authorities, Dr. John Anderson and I drew attention to the frequency with which cholesterol deposits were found in the intima of the carotid sinus, even in very young infants. "The degenerative changes in the vessel wall are usually seen to the naked eye, the carotid vessels in a number of cases showing rows of fatty elevations of the intima as large as a pin head. These vessels, often omitted from routine *post-mortem* examination, show changes more commonly than others in status lymphaticus, especially at and just above the bifurcation."

As no agreement about the size and weight of a "normal" thymus is ever likely to be achieved, and as the trend of all modern opinion is against the thymus gland having any immediate relationship to the cause of death in cases of this kind, investigation of how far the involvement of the tunica intima by pathological infiltrations would alter this reflex during anaesthesia or under other strain, might provide a most fertile field for study and from a medico-legal point of view might be of far-reaching importance and value.

There are probably other areas of the arterial tree where similar reflexes have their origin, for instance, where the coeliac artery divides. This is another situation where involvement of the arterial wall is often found in sudden death—I am, etc.,

Victoria Infirmary, Glasgow, July 26th

J. A. M. CAMPLING

PROTECTION OF THE MEDICAL PRACTITIONER
SIGNING LUNACY CERTIFICATES

SIR—The first resolution of the Bournemouth Division—

"That in regard to Section 330 of the Lunacy Act 1890—(a) the onus of proof of want of reasonable care and want of good faith should be on the plaintiff, (b) unless the plaintiff can satisfy the judge that he is able to prove in a court of law the want of reasonable care and good faith the case should not proceed to trial, and (c) the judge should be able to call in expert opinion on the point of reasonable care in respect of medical certificates if he himself is in any doubt—"

does not give the protection which was intended when the bill was introduced, nor that which medical men are entitled to demand. When the Act of 1889 was introduced into the House of Lords Lord Halsbury said that one of the points in the bill was the protection of medical men and others against vexatious actions where they have acted in good faith, and the Home Secretary Mr. Matthews, stated on June 3rd, 1889, in the House of Commons, that a new feature had been introduced into the bill—namely, that there should be an inquiry before a permanent judicial tribunal. In order to obviate the evils of vexatious actions against medical men, and also to provide a security against any possible abuse of the anomalous privilege which medical men have so long enjoyed, it is provided that a judicial inquiry shall be held and a judicial decision obtained before a person can be permanently confined as a lunatic.

It is clear, therefore, that it was the intention of Parliament to give complete protection to the medical man signing a lunacy certificate, and apparently it was needed then, for Dr. Farquharson said that doctors at that time were in such dread of legal proceedings that they hardly ventured to certify lunacy at all. This is exactly the position we are in now, and the judicial tribunal which was set up to protect us and to ensure that our certificate might

not be the cause of the detention, has failed, because under Section 330, Clause 2 states that in order to arrest proceedings we have to satisfy the judge that there were no grounds for alleging want of good faith or reasonable care. "Reasonable care" was a most unfortunate phrase, for what might appear as reasonable care before an event might look very foolish afterwards. It would require something approaching infallibility to be able to convince the judge that there was no want of reasonable care, there have been, consequently, quite a number of vexatious actions.

I trust, therefore, that the Bournemouth resolution will be so strengthened that when a medical man has undertaken the unpleasant duty of issuing a lunacy certificate in the interest of his patient and the public he will be able to feel confident that while he acts in good faith he will not be liable to vexatious litigation, even if he has made an error of judgement—for who is infallible?—I am, etc.,

W. R. WILSON, D.P.H., F.R.C.S.I.

Bournemouth, July 10th

THE MERCURY BAG

SIR—Dr. Douglas Smith, in his interesting note (July 14th, p. 53), draws attention to a method which is capable of rendering wider service than he indicates. It has been used in Dundee Royal Infirmary since, about twenty-five years ago, I took it to replace compression by a shot-filled condom for persistent pelvic infiltrations such as haematomata. It has been employed with success for such cases and also as Dr. Smith uses it for the incarcerated retroplaced uterus. On one occasion it enabled me to return an inverted uterus. The large Barnes's bag is suitable, and is easily laid transversely in the posterior fornix. The barrel of the old glass methral syringe is a convenient funnel by which to pour the mercury into the tube. In using the method the fact that mercury in bulk feels rather cold is worth remembering. The available stock of mercury should be about four pounds—I am, etc.,

Dundee, July 16th

R. C. BUIST, M.D.

RESULTS OF TREATMENT OF UTERINE CANCER

SIR—I have received by post a pamphlet entitled "The Radium Treatment of Cancer of the Uterus," published by the Cancer Research Committee of the London Association of the Medical Women's Federation, which is said to be a report of that committee to the Medical Research Council and the British Empire Cancer Campaign. On page 8 is a table giving certain statistics relating to the radical surgical treatment of cancer of the cervix. In that table I am stated to have operated upon "90 cases out of a total of 150 cases seen, with a primary mortality of 20 per cent and a five-year cure rate of 40 per cent, and an absolute cure rate of 26.6 per cent." In a bibliography appended a few pages later my report is stated to have appeared in the *British Medical Journal*, 1925, vol. II, page 282.

Being unable to recognize the figures attributed to me, I looked up my original article according to the direction in the bibliography. I delivered it at Bath in 1925 at the Meeting of the British Medical Association, where I introduced the subject of the surgical treatment of malignant disease of the uterus at the Section of Obstetrics and Gynaecology. The figures that I gave on that occasion were as follows: 182 operations out of 303 cases seen, with an operative mortality of 16 per cent, a five-year cure rate of 40 per cent, and an absolute cure rate of 25 per cent. These figures are given so clearly that no one reading the paper, even hurriedly, could be in any doubt about them.

Under the table referred to it is stated that "records of more recent cases by Wertheim and Bonney give the primary mortality as 8 per cent and 16 per cent respectively." As regards Wertheim's figures, all that can be said is that as he died many years ago, and his latest results were published many years ago, there seems no legitimate reason why they should not have been quoted in preference to those older figures which appear with his name in the table referred to. As regards myself, it would appear that the writer of the pamphlet knew that in 1926 I read at the Section of Obstetrics and Gynaecology, and subsequently

¹ Status Lymphaticus and Sudden Death. *Glasgow Medical Journal*, September 1927.

published in the *Proceedings of the Royal Society of Medicine*, an article dealing with 214 patients operated on out of 340 patients presenting themselves, with an operative mortality of 15.8 per cent (12 per cent in the last 114), a five-year cure rate of just under 40 per cent, and an absolute cure rate of 25 per cent.

The pamphlet in question, since it was accompanied by a leaflet making a special appeal for money for which a form of donation was attached, has presumably been circulated with its inaccurate figures amongst the general public. This is bad enough, but, more than that, it is a report to the Medical Research Council and the authorities of the British Empire Cancer Campaign. At the outset of the pamphlet it is stated, "*great care* was necessary in making a comparative study of the reports of the surgical and radium treatment of uterine cancer." This is perfectly true, and therefore the least that can be said is that these misstated figures are an instance of gross carelessness.

I seem to be unfortunate in this matter, for it was only in August last year that I and my colleague Mr Comyns Berkeley had to protest in your correspondence column against the inaccurate use made of our figures in the review of cancer of the uterus published by the Ministry of Health, and written by Miss Lane Claydon, M.D.—I am, etc.,

London W, July 17th.

VICTOR BONNEY

THE ETIOLOGY OF MONGOLISM

Sir,—The great majority of the cases of Mongolism which I have observed can be placed in one of the following groups: the first child of a very young mother, the first and only child, often, but not always, born of a late marriage, the last child of a family, generally born of a mother nearing the menopause.

I suggest the theory that there are five phases in the life of each ovary: (1) The period of immaturity. (2) A short period of pre-maturity, in which the ovum is fertilizable but incapable of developing into a perfect embryo. (3) The period of sexual maturity. (4) A short period before the menopause in which the ovum is still fertilizable, but no longer capable of producing a perfect embryo. (5) The period of final degeneration after the menopause.

The phases (2) and (4) are obviously those in which there is a risk of producing the Mongolian type; pathological degeneration of an ovary might occur at any period of the sexual life, thus accounting for the relatively common Mongol only child. There is no reason to suppose that both ovaries must degenerate simultaneously, so the occurrence of two, but only two, Mongols in one family is theoretically possible.

Dr Armstrong (whose paper appeared in the *Journal* of June 30th, p. 1106) will be interested to know that I have such a case under observation at the present time. There were seven children of the marriage, the fifth and seventh were typical Mongolian imbeciles, but the sixth was a normal child. The mother was 40 years old at the birth of the fifth child.

The theory which I have vaguely outlined would be invalidated by a proved case of uniovular twins, of which the one was a Mongol and the other a normal child—I am, etc.,

Leicester July 1st.

J. M. MACKINTOSH

SHOCK AND ABORTION

Sir,—In view of the letters on this subject published on February 25th (p. 327) and March 3rd (p. 375) the following occurrence may be worth recording.

The coroner asked me to investigate the cause of death in a woman, aged 36, who was found dead in her bedroom with a bowl containing soap solution and a Higginson syringe under the bed.

At the necropsy she was found to be a healthy woman and the stomach contained a large undigested meal. In the uterus was a foetus of the age of 15 weeks. Between the membranes and the uterine wall there was a full half pint of soap solution, containing some undissolved soap shavings. The solution was so strong as to be like a thick paste. The

os uteri was undilated, and there was no haemorrhage. Except that the blood and endocardium had a lavender-like tinge, there were no macroscopic changes in the organs.

The history was that she ate a meal at noon and went to her bedroom. At 1 p.m. she said she was not well, she asked for tea, but died before it was prepared, giving a few gasps and falling back on the bed.

It seemed incredible that undissolved soap shavings should pass the valve of a Higginson syringe and an undilated os, but I find that it will—I am, etc.,

London E.13 July 8th

A. C. KENNEDY

VOLUNTARY HOSPITALS AND THE STATE

Sir,—The agenda for the meeting of the Marylebone Division on June 28th had the following item:

ANNUAL REPORT OF COUNCIL (in large type)

Adjourned discussion

Notice of Amendments have been received from

1 Dr David Roxburgh

2 Dr Graham Little, M.P.

Mr Eccles suppresses the material fact that my amendment was, as announced, an amendment to the Annual Report of Council, and describes it as "cryptic" and "secret." Of course, I am not responsible for the form which the agenda took, but I do not think that his epithets are justified.

The figure of 1,500 as being the number of invitations sent out was given to the meeting by the secretary and quoted by me on that authority. Since that date the secretary has informed me that the number was "nearer 1,200 than 1,500." It is Mr Eccles who is in greater need of correction on this point than I.

With the agenda paper a leaflet was issued notifying these 1,200 recipients that the Division would proceed to nominate two direct representatives upon the General Medical Council. The business of the meeting, therefore, was perhaps of rather especial importance, and I submit that an attendance of 11 out of 1,200 summoned demonstrates a regrettable indifference, almost amounting to a boycott of the Marylebone Division by the practitioners residing in Marylebone, who consist so largely of consultants.

Mr Eccles claims that the scheme of the Hospitals Committee over which he presides restricted the functions of the "Central Authority" to advice only. Unfortunately for his contention, however, the Appendix to the Annual Report of Council goes on to say that the "hospital grouping which the Association envisages would be on lines similar to those suggested in the Interim Report of the Consultative Council on Medical and Allied Services, 1920." Reference to the report thus named, I think, disposes of the suggestion that the Central Authority would be content with giving advice only, whatever might be the desire of the Hospitals Committee. It is expressly set out in the recommendations of that Interim Report that by the operation of the scheme recommended, all the medical services, including the teaching and other voluntary hospitals, would be "brought together in close co-ordination under a single Health Authority for each area." Again, "It is vital to the success of any scheme of Health Service that there should be unity of idea and purpose, and there will be need for a new type of Health Authority to bring about unity of local control [the italics are mine E.G.L.] for all health services, curative and preventive." The composition of the health authority recommended by the Interim Report is set out in Section 28: three-fifths of the membership was to be constituted "by representatives elected by popular vote" (presumably by the same method as Poor Law guardians have been elected), and the other two-fifths, it was suggested, "should be persons whose special knowledge of health questions would be of value." The report expressly says "By such an arrangement the elected representatives would hold the majority of votes and the nominated members would contribute to the skilled knowledge necessary for successful deliberation." Inasmuch as the Ministry of Health inherits the wide powers of the Local Government Board the "representatives elected by popular vote" would be under the authority of the Ministry. Surely my view that the control of all the

hospitals thus co-ordinated would under this scheme ultimately pass to the Ministry of Health is amply justified.

The discussion at the Marylebone Division disclosed some interesting discrepancies in the views of the two protagonists of the Council who were present. The Treasurer described the scheme detailed in the Appendix as "a subtle manoeuvre," as "an astute political move," designed rather to outwit the enemy than to afford a really satisfactory solution of the problem, statements for which he was reprimanded by the Chairman of the Hospitals Committee, whose overweening self complacency prevents him from seeing the report of his committee otherwise than as a "carefully thought out scheme for the co-ordination of hospital provision." But if the Hospitals Committee can do nothing better than to reproduce in its essential features a scheme for co-ordination of medical services which fell stillborn upon its production in 1920 and has never exhibited any signs of life since then, they surely write themselves down as being singularly empty of initiative or statesmanship. By resuscitating this scheme the Hospitals Committee are doing their best to supersede the voluntary system by bureaucratic and ministerial control.

It is interesting to note that the signatories of the much more important letter which follows that of Mr.icles in your issue of July 14th from the President, Chairman of the Council, and Chairman of the Weekly Board of the Chelsea Hospital for Women, take the view which I have ventured to urge. They say "The time would seem to be ripe for the representatives of the London hospitals to devise a scheme under which the voluntary and municipal institutions could work together without the loss of the voluntary management and support." It is with the object of stimulating the "representatives of the London hospitals" to combine in opposition to these insidious attacks upon the voluntary system that I am moving my amendment at Cardiff. I have received notice that the Hampstead Division has instructed its representatives to support that amendment, and I hope other Divisions will take the same action—I am, etc.,

London, W 1, July 16th.

E. GRAHAM LITTLE

CARE OF THE HEALTH OF MERCHANT SEAMEN

SIR,—I venture to submit again that the British Medical Association should consider the case of merchant seamen, and adopt some means for forcing the hand of the Board of Trade to compel the Board to hand over the responsibility for the health of the 200,000 merchant seamen to the Ministry of Health.

Merchant seamen, as regards their health, are hardly treated fairly by the State. No one is made definitely responsible for their health, but the Board of Trade has for years recorded their deaths, and, by its surveyors, exercises control over the building of ships and so over the accommodation and sanitary conditions under which seamen live. Their deaths are reported to the Board of Trade, but come under no medical scrutiny, the Board having no medical official of the standing of a medical officer of health. As a result, no annual report about their health is published—nothing resembling the annual reports of the chief medical officer of the Ministry, or the health reports of the services, which reports, between them, cover the health of all men in England and Wales except the merchant seamen.

No valid excuse for such neglect can be seriously offered to the medical profession, particularly as the enteric death rate of seamen has only fallen by 50 per cent in twenty-five years, but everywhere else in this country, in the same period, by 90 per cent, as I hope to show in a paper to the Royal Sanitary Institute this week.

The deaths of landsmen assist the sanitary branch to lower the death rates of their successors, but it is not so in the merchant service, where death rates fall by reason of sanitary research conducted in relation to people on shore, not among seafarers, there being no co-ordinating authority to study the diseases of merchant seamen as a whole. The fullest knowledge of the diseases of seamen and the measures due for their prevention is that possessed by the medical officers of health of the port sanitary authorities, who hear from each ship as she arrives what

diseases have occurred during her voyage, and learn, by then on immediate inspection, the sanitary state of the ship when she is working (Board of Trade surveyors are by their own instructions forbidden to inspect ships unless they have been cleaned). Now these medical officers of health are officers reporting to the Ministry of Health, not to the Board of Trade, and they publish most valuable reports, but there is no superior co-ordinating official to furnish each year a summary of the conditions most usually or, as the case may be, exceptionally found—a health report, in fact, for the merchant service. I submit that a health superintendent is needed for the merchant service, to whom the Board of Trade would communicate the reports of deaths as they arrive, and he will do better work at the Ministry, among professional brethren, than if he were to be marooned at the Board of Trade. From next year on it will be easier, I understand, for him to prepare an accurate death rate, for the seamen's national health insurance organization will be able in that year to state the number of crew days served on articles, and a death rate for the merchant service will be as attainable as now for the Royal Navy.

I submit that a report published annually on the health of the merchant service will cause greater advance in ten years than without it will come in fifty. All changes are difficult. The slightest would be to have the Board of Trade send the notices it gets of seamen's deaths over to the Ministry of Health, to be considered there by a skilled official to collate with them the reports of the medical officers of health of port sanitary authorities into an annual report on the health of the merchant service. Why should the Registrar General be able to say, as he does in his last decennial supplement, "the seaman's mortality from disease exceeds the average by 48.8 per cent, and his mortality from violence by 430 per cent"? Surely it is work for the medical profession to stop that—I am, etc.,

W. E. HOME,
Fleet Surgeon.

New, July 16th.

DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL

SIR—I must apologize for sending such a long list of "experience in public and medico-political work" for inclusion in your columns with the list of nominations for election to the General Medical Council (Supplement, July 14th, p. 18). Apparently the exigencies of space required considerable curtailment, and unfortunately, in pruning the tree, some branches were lopped off which to me appear to be of prime importance. I would therefore ask you to be good enough to supplement the record you kindly inserted by adding to it the following items.

I have been in general and surgical practice for upwards of thirty-four years.

As well as being on the staff of the Victoria Hospital for Children, Hull, and that of the Hull and Sculcoates Dispensary, I am a member of the boards of management of both institutions, and a trustee for the latter.

I was a founder of the Hull Medico-Ethical Society (now Medical Society), and president in 1897 and a founder (and trustee) of the Medical Benevolent Society for the North and East Ridings of Yorkshire.

I served on the Medical Acts Amendment Bill and on the Coroners Act Amendment Bill Committees of the British Medical Association.

I was a D.C.M.S. and liaison officer between the Ministry of National Service and the Central Medical War Committee, British Medical Association, and was Commissioner of Medical Services and Deputy Regional Director for the Yorkshire Region, Ministry of Pensions.

The most important of the omitted items is that I am a vice-president and have been for many years a member of Council (with 100 per cent of attendances) of the Medical Defence Union. Thus, I submit, in conjunction with my membership of the Central Ethical Committee, British Medical Association (also with 100 per cent attendances), has given me experience in considering, and dealing with, cases of alleged professional misconduct which I do not believe any other candidate has had, except Mr. E. B. Turner, when he was previously a member of the General Medical Council—I am, etc.,

Harrrogate July 14th.

C. H. MILBURN

Obituary.

WILLIAM DYSON, M.D.,

Emeritus Professor of Medicine, Sheffield University, and Consulting Physician, Sheffield Royal Infirmary

By the death of Dr. William Dyson on July 9th the city of Sheffield loses a useful citizen, the medical profession a recognized leader, and the University an Emeritus Professor of Medicine of distinction. His death at this time cast a gloom over the celebration of the centenary of the medical school to which he had given such great service in the past.

William Dyson was born at Thurgoland, Yorks, on July 15th, 1849. He was one of a large family well known in Wesleyan circles, being the son of John Dyson, J.P. He was educated at the old Wesley College, Sheffield, and graduated B.A. Lond. in 1868 in his nineteenth year. He entered University College, London, in the following year as a student of medicine, his career there was most successful, and he had as fellow students Sir Thomas Barlow and the late Professor W. S. Greenfield of Edinburgh. He was a favourite pupil of Sir William Jenner, and in after years he often spoke in affectionate terms of his famous teacher of clinical medicine. He graduated M.B. Lond. in 1873, with honours in medicine and midwifery, and obtained the diploma M.R.C.S. in the same year. For a time he held the posts of physician's assistant and obstetrical assistant at University College Hospital, and in 1874 he proceeded M.D. Lond. He next practised in his native village for a short time, but removed to Sheffield in 1875, by the time he was 30 he had acquired a large consulting practice in this town and the district around. In 1876 he became physician to the Sheffield Hospital and Dispensary (now the Sheffield Royal Hospital), in 1885 he was appointed physician to the General Infirmary (now the Royal Infirmary), and for twenty-seven years rendered great service to this institution, retiring in 1912 as consulting physician.

In the Sheffield Medical School, which has just celebrated its centenary, he took a lively and practical interest. After holding positions of a minor nature he became lecturer in physiology in 1882. In 1885 he was appointed joint lecturer in medicine, and in 1886 was elected president of the school. It was during this period (1888) that the old school in Surrey Street was transferred to more commodious quarters in Leopold Street. In 1897 the school became part of the new University College, and Dyson was appointed the first professor of medicine. Together with the late Simon Snell and the present professor of medicine, Dyson played a prominent part in the attempt made to obtain a charter for a university in Sheffield. The project materialized in 1905, and Dyson, having already resigned his chair, was appointed Emeritus Professor of Medicine as an acknowledgement of his great services to the school in the past. As a teacher Dyson was deservedly popular, and a strong bond of affection was formed between "Billy" and his students. At the celebrations on July 11th many of his old students were present, and numerous kindly remarks of sorrow were voiced at his passing at this time. The Chancellor of the University (the Marquess of Crewe), before formally opening the congregation, paid a graceful tribute to the service that Dr. Dyson had rendered to the University.

In the British Medical Association he was always to the fore. He was a member of the Central Council from 1896 to 1903. This was an important period in the history of the Association, which was then being reorganized into the splendid body which it is to-day. The great interest which Dyson took in the decisions of that time is well remembered. He was also president of the Yorkshire

Branch in 1895, having been a member of the Branch Council since 1888, and a vice-president from 1897 to 1925. In 1908, when the Association met in Sheffield, he was president of the Section of Medicine, and in 1881 he was president of the Sheffield Medical-Chirurgical Society.

Dyson was specially successful as a diagnostician, and was rarely at fault. His methods resembled those of the clinicians of last century, and he relied chiefly on his powers of observation and his great experience. His contributions to medical literature include the report of a case of haemoglobinuria (*British Medical Journal*, 1885), and a paper on acute dilatation of the stomach. He was also an early writer on myxoedema and acromegaly when these diseases were exciting great interest in the early nineties. For many years he had the bulk of the consulting field to himself, travelling many miles daily in Sheffield and the moorland districts around in all sorts of weather. In this connexion the older men will remember "Joe," his coachman, who was with him for over thirty years, and who, with his "wo" when answering inquiries, was a well known character.

In the public life of Sheffield Dr. Dyson played a prominent part. He was made a magistrate in 1902, and was also a member of the Town Trust.

Generous to a fault, he supported every good cause, many a lame dog has been helped over a stile by a timely cheque from Dyson. His hospitality in private days—particularly to country doctors who seldom met their colleagues—was bountiful. About 1912 his health began to fail and he gradually withdrew from practice. He lived, however, almost to his eightieth birthday, and saw nearly all his contemporaries pass away before him. He was fond of music, and was an accomplished organist. He composed one or two settings for hymns which were published, his musical ear enabled him to imitate many of the calls of the commoner birds. In his earlier years he was a cyclist, especially during his holidays. He married Miss E. J. Andrews, daughter of Thomas Andrews of Wortley, and sister of Thomas Andrews, F.R.S., the well known engineer. They celebrated their golden wedding in 1925. He is survived by his widow, one daughter, and

William Dyson, M.D.

Another son in the medical profession. Another son was killed in the war.

Dr. Dyson was interred at Ecclesall Church on July 11th in the presence of many public men, old friends, and patients. Many of his old students absented themselves from part of the centenary celebrations in order to pay their last tribute to one who played a great part in the development of the School of Medicine of Sheffield.

The photograph reproduced is by G. T. Y. Dickinson, Sheffield.

We regret to record the death, on July 2nd, of Dr. JOHN INGLIS PARSONS, at his residence in Bournemouth, at the age of 71. He received his medical education at Guy's Hospital, graduating M.B. at the University of Durham in 1883, and proceeding M.D. in 1886, six years later he obtained the diploma M.R.C.P. Lond. After serving as house-surgeon at Guy's Hospital he was appointed assistant surgeon to the Chelsea Hospital for Women in 1886, and throughout the remainder of his life maintained the keenest interest in this institution, to which he was subsequently appointed surgeon, and later consulting surgeon. He published numerous articles in the *British Medical Journal* and elsewhere on gynaecological subjects. He also took particular interest in the applications of electricity to treatment, particularly in gynecology, and was a member of the American and French Electro-Therapeutic Societies. Other appointments held by him included those of surgeon to the Royal Maternity Charity, and lecturer on medicine to the Zenana Medical College.

Dr JAMES DEWAH, who died at St Margaret's Hospo, in the Orkneys, on July 11th, had spent nearly sixty years as a practitioner in those islands, and retired only a few months ago, when he took up his residence at Pochahers, Morayshire. After graduating in arts at Aberdeen University in 1866 he pursued his medical studies in that city, graduating M.B., C.M. in 1870. He then, following the custom of the times among newly qualified medical men in the North of Scotland, undertook a voyage to Greenland as surgeon in a whaling ship. On his return he commenced practice in South Ronaldshay, in the Orkney Isles, where he was provincial medical officer for the exceptionally long period of fifty-six years. When he retired last May his services were recognized by his island patients and friends by the presentation of an illuminated address and other gifts. He was a member of the British Medical Association.

Dr JOHN TAIT, whose death occurred suddenly at his residence at Moffat, in Dumfriesshire, on July 12th, was the son of a solicitor in that town, and was born in 1861. He received his medical education at Edinburgh University and Owens College, Manchester, and in 1893 obtained the diplomas L.R.C.P., L.R.C.S. Ed., and L.R.F.P.S. Glas., subsequently commencing practice at Altham, in Pethshire, where he spent the greater part of his professional life. He was for many years a keen member, successively, of the Volunteers and the Territorials, and attained the rank of lieutenant-colonel in the Royal Army Medical Corps, serving in this capacity throughout the war. After the conclusion of hostilities he gave up his practice, and was employed by the Ministry of Pensions. His later years were spent at the place of his birth.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

In the House of Lords, on July 16th, the Reorganization of Offices (Scotland) Bill was read a second time.

On July 17th the House of Commons read the Rating and Valuation (Apportionment) Bill a third time. On subsequent days the Racecourse Betting Bill was considered, and the week closed with a debate on the reports of the tribunal of inquiry into the examination of a witness at Scotland Yard.

The Parliamentary Medical Committee met at the House of Commons on July 17th. It discussed the rating of hospitals, which had been debated in the House of Commons on the previous day. The committee decided to approach Mr Chamberlain and ask him to institute an inquiry into the dangers arising from artificial sunlight treatment and into the frauds sometimes associated with its commercial exploitation, with a view to the control of such treatments by registration or otherwise. The committee discussed the Chiropractors Registration Bill, which has been introduced in the House of Lords, but decided to take no action.

Dogs (Amendment) Bill

In the House of Lords, on July 16th the third reading of the Dogs (Amendment) Bill, which has passed the House of Commons, was moved, and a debate arose on vivisection.

LORD BANBURY moved the omission of Clause 2. He said that under the Act of 1906 Clauses 3 and 4 must be read together. This bill proposed to leave out Clause 4 and to substitute for it another clause which he (Lord Banbury) proposed to leave out. That would leave the law in exactly the same position as it was now. Clause 4 of the Act of 1906 said that 'Any person who takes possession of a stray dog shall forthwith either return the dog to its owner or give notice in writing to the chief officer of police of the district where the dog was found.' Clause 3 which must be read in conjunction with it said 'Where a police officer had reason to believe that any dog found in a highway or place of public resort is a stray dog he may seize the dog and may detain it until the owner has claimed it and paid all expenses incurred by reason of its detention.' Subsection (5) said 'No dog so seized shall be given or sold for the purposes of vivisection.' That was the law as it stood now. In February of this year a bill was introduced in the House of Commons the chief object of which was to make owners of dogs liable for injury to poultry. To that he had no objection. But it then went on to repeal Section 4 of the principal Act, which he had just read and to substitute this: 'Any person who takes possession of a stray dog shall forthwith either return the dog to its owner or deliver the dog to a police officer of the police area in which the dog was found and inform that officer where the dog was

found.' The clause further said 'A dog which has been delivered to a police officer under this section shall be treated as if it had been seized by that officer in pursuance of Section 3 of this Act.' That was to say that if any dog was seized by a police officer it should be treated in pursuance of the Act of 1906 with the result that no stray dog or lost dog which was taken to the police would be used for the purpose of vivisection. That was the bill as introduced in the House of Commons and as it passed the second reading and the Committee stage. On the Report stage, however, an amendment was moved to leave out the clause and insert another one which was in the bill now before their lordships. The effect of that clause was that the protection which existed at the present moment against the use for vivisection purposes of a stray or lost dog was done away with. Under the clause which he proposed to leave out there were two alternatives. A person who found a stray dog had to take it to the police station. If that person did not want to keep the dog the police took possession of it and they could not sell it for the purposes of vivisection. On the other hand, if the person who found the dog was a person whose object it was to look for stray or lost dogs in order to make money out of them by keeping them for a month and then selling them for the purposes of vivisection what was to prevent him? If a person was not very scrupulous, and he found a dog with a collar on it he could remove the collar and throw it away before taking the dog to the police station. In that case the identification of the dog was to a certain extent lost and the profit which the man was going to make was pretty sure. Knowing human nature and bearing in mind a case that occurred not very long ago when two dogs were found in a sack and another case in which a dog had been taken off the doorstep of its owner, and where they were all found at an institution where vivisection was carried on he said that it was pretty certain that under this alternative of the law there would be people who would take advantage of it for the purposes which he had suggested. He hoped the House would support him because this was an insidious attempt to do what had been attempted for some time and had failed—that was to obtain all stray or lost dogs for the purposes of vivisection.

LORD DAWSON OF PENN said that they had to consider two varieties of dogs. One was the owned dog. Was there any member of that House who would not take any precaution necessary to preserve the owned dog to its owner? Then there was the stray dog which wandered about asking out such a living as it could, uncared for a misery to itself and a danger to the community. Each year something like 30,000 stray dogs were destroyed in the city of London alone. Was it not obvious if there was to be the same provision for both varieties of dogs that the owned dog would suffer? If they put an embargo on the use of the stray dog for experimental purposes would they not correspondingly endanger the owned dog? The bill provided extremely well for that contingency. Its provisions would help in the identification of the owned dog and diminish the chances of mishap. Therefore it deserved the support of that House. It was clear that the object of Lord Banbury was not the protection of the owned dog. Underlying all Lord Banbury's remarks was this, that he was making this an opportunity for a flank attack on the use of dogs for experimentation. He (Lord Dawson) would take up his challenge for it was clear enough that the question of experimentation on animals stood or fell by the use or not of dogs. Which ever way they approached this question of experimentation on dogs surrounding it by as much misrepresentation of fact as they would—and there was no subject he knew of which was more misrepresented—they always arrived at two aspects of the question. The first was 'Do material advantages accrue to mankind from experimentation on dogs and experimentation on animals in general?' The second question a totally different one, was 'Whatever those advantages may be is it ethically justifiable that mankind should take advantage of them?'

The first question, whether material advantages accrued to mankind, was surely a question for those people with skilled knowledge. There was no one else who could give the answer. Yes or 'No.' Supposing, for example, that they were building a bridge across a river. They might decide the policy as to whether the bridge should be built or not but whether the bridge should be built of chrome steel or manganese steel or whatever the distribution of the stresses should be would be left to the engineers. The problem of the engineer was nothing in comparison with the problems which arose in connexion with the body and mind of man. It was a remarkable fact that while it was usual to find experts differing materially on this question of experimentation on dogs there was such a consensus of opinion among the medical men of the civilized world that it amounted to practical unanimity. They had recently had a conference representing every aspect of medicine and surgery and of the sciences on which medicine and surgery rested. A more representative conference there could not be and that conference said this to the British nation. 'That without experimentation on animals medicine and surgery could not carry on. He did not mean that they would not carry on—of course they would do their best—but intellectually we should come to stagnation. He would put the matter in another way. Supposing he was asked to find a staff for a hospital of, say, 200 beds in London and had to find surgeons and physicians of sufficient standing for the purpose who would embrace the principles that Lord Banbury advocated. He had to tell the House that he could not find such a staff. It did not exist. That would indicate to what extent unanimity existed among members of the medical profession on this question.'

The only honest opponents were those who approached the question from the ethical standpoint. He had in mind the man who said 'Whatever the advantages that accrue to mankind, it is ethically unjustifiable that you should make use of them.' He respected that man provided that he did not himself make use of those remedies in his time of trouble. It was a question

for the public. They invited the public to answer that question. It was for them to say "Yes" or "No." If they said "Yes" by all means let them have the legislation which would make all these things illegal. That at any rate would be an honest and straightforward course. If on the other hand the answer was "No" no one would wish to stop these things, then he said:

For Heaven's sake leave us alone to go on with our work and do not harass us day by day and year by year. What was true of the dog was true of other animals. The medical profession told the House, with a real sense of responsibility, that they could not do without dogs—that they could not substitute other animals in every case. Their universal rule was that they never used an animal higher in the scale of creation than was absolutely necessary. They used the lowest animal possible compatible with doing their best and getting successful results.

In order that the public might be in a position to answer the question whether it was ethically justifiable, it would be of some profit if he tried to clear away a few misconceptions. Take the question of pain. Was it likely that those whose upbringing had been in association with pain from their student days were going to do anything which would needlessly increase pain when their whole careers were spent in assuaging it? They were not likely to be less sensitive than Lord Banbury on the question of inflicting pain. On the contrary, they knew more about it and what it meant. Therefore he would not waste time in dwelling upon any question of indifference of the medical profession to pain. As to the 30,000 animals that were anaesthetized every year, all they asked was that they should be made of use not only for the benefit of mankind but for themselves. It must be borne in mind that the large majority of experiments on animals were carried out under anaesthesia and the dogs and other animals were completely ignorant of what was going on.

He would admit that there were a minority of cases where animals were given diseases in order to aid in the diagnosis of disease in man. He admitted further that there were from time to time what they called survival experiments. He would tell their lordships exactly what survival experiments meant. The greater part of the treatment of gastro-intestinal disease in modern times depended mainly upon experiment on animals. One of the most distinguished men of modern times was Professor Pavlov of Russia. As an example let them take the case of a man who was going to be short-circuited for duodenal ulcer. They might take his pain and distress and divide them into three parts. There was first the stage of anticipation. There was that stage when he had to make up his mind to face the risks to himself and his family. All these agonies of mind far exceeded distress of body. Man had to go through all that, not the animals. The animal had none of that. He had no power of anticipation whatever. The second stage was that of the actual operation of short-circuiting. There the man and the animal were on a par. They were both under anaesthesia and both felt nothing. The third stage in some respects the most distressing of all, was that terrible process of building up the man's health after illness the time of shock, of convalescence. Let them contrast man and animal there. The man might be weeks and months before he was well. In the case of the animal what happened? They might have an operation on a dog for short-circuiting and the same day it would be playing about with its owner. In the case of an experiment on a monkey he had himself seen the animal within twenty-four hours sitting on his perch eating a banana. That horrible process of getting well of recovering from shock was entirely unknown to the animal.

The fact was that it was a slavery of terms. If they read in the papers that one of their lordships had been vivisected and that his appendix had been removed they would be distressed and horrified. But if they read that he had been operated upon they would think nothing of it. There was no difference between the one and the other. What had happened to the animal had happened to the man, but what happened to the man was tenfold or a hundredfold greater than what happened to the animal.

It was necessary to understand what the implication would be if a measure for suppressing experimentation on animals were passed. It would affect the whole range of medicine—the diseases of the gastro-intestinal tract, typhoid, lockjaw—he could go on with a list which would occupy too much of their attention on an afternoon like that. Much of what we knew about gall-stones dogs had told us. Take jaundice including the malignant jaundice of dogs. Whereas at one time a dog stricken with malignant jaundice nearly always died, since the discovery of trypan blue the majority of dogs stricken with this disease were saved. In the investigation of disease that animal had to be used which the particular problem required. For instance for the investigation of infantile paralysis the monkey was the only animal which it was of use to employ. Again take the case of tetanus. In the war they had more experience than they wanted of that terrible disease. He would not wish that anybody should experience what that disease was. It was important for people to know the consequences of removing from medicine all these results based on experimentation on animals. They had only got to be understood by the public, and then he had no doubt what the public would say. This result would have happened long ago but for the fact that the propagandists against vivisection were not themselves subject to their own gospel. If a propagandist against vivisection was stricken with any of those diseases he gave an implicit, if not an explicit consent to vivisection. If those who were against all experimentation on animals were in their own persons or in their own families afflicted with disease did their lordships for one moment suppose that they did not adopt the remedies which were based on experimentation? He could assure them that with few exceptions they did adopt them and was it to be wondered at? Imagine the crisis of love and life in the

balance, the crisis of anxious illness. At such a time the theories of the comfortable armchair gave place to more common-sense and reasonable ideas. He would not be hard on their inconsistencies. After all, one did not expect human beings to be consistent. Life would be a drab and dreary business if we were always consistent. If the uses of new drugs could not be worked out on animals, the alternative was to work them out on human beings. Perhaps Lord Banbury would form a band of people of conscientious convictions who would allow the medical profession to work out new drugs on them! When it came to working out new drugs like pituitrin, adrenalin, and digitaline, the question was whether it was better to work them out on animals before they transferred their use to human beings. He would not say anything against inconsistency if in the hour of trouble the philosophy of antivivisection broke down. He would think humanly of that, but what surpassed the limits of tolerance was that these people could get these remedies when they liked, and yet they were constantly disturbing the minds of unknowing and innocent people in our hospitals in order to prevent these remedies reaching them.

All hospitals in this country were up against the difficulty of getting funds at the present time. They made an appeal in their distress and then along came these fanatical people. They put advertisements in the daily press they inveighed against the hospital, they sent letters to all the subscribers, and they did their best to spoil the appeal for funds. They appealed to the ignorant and the heedless by misrepresentations which might be called gross and by that means they were destroying the flow of charitable funds. Yet let one of these propagandists himself be ill and all he had to do was to go to a private doctor and not suffer at all. They might take it that that was the general rule. He would give an example. They had the terrors of lockjaw in the war when they found people dying of convulsions which could only be described as agonizing because they were continuous right up to the point of death and consciousness was preserved up to the point of death. They adopted the plan after most interesting investigations, of using a serum against lockjaw. The effect on the mortality from tetanus in the war was that it came down to quite small proportions. Since the war it had been the practice for all well-ordered hospitals to have constantly in stock antitetanic serum because street accidents were brought in from time to time and it was the rule that directly a street accident was brought in antitetanic serum was injected. That was contrary to the principles of the antivivisectionist. There was a hospital in London where they would not use antitetanic serum. A street accident was brought in and they refused to give the serum and the patient died of lockjaw. What was more two other patients subsequently died of lockjaw at this hospital, and they called that hospital a charity! He called it a place for propaganda and nothing more and he hoped that King Edward's Fund would take note of this episode and would not give that hospital a certificate that it was a charity ready to treat the maimed and the wounded by the best methods known to science at the present time. At the same time as these poor people the workers who had no choice where they should be taken were taken to this hospital would the governors of the hospital or their children if they got an injury in a street accident go without antitetanic serum? Not at all they would go home and call in their private doctor and it would be given.

The fact was that it was an impossible situation. What it amounted to was that these people were practising their theories on the dog only this time it was being tried on the human dog and the world suffered thereby. He put it to their lordships that the health of the nation was a momentous matter not to be treated lightly, but to be treated seriously and not made the playing ground of vain imaginings of misguided thought, and he asked the House to reject Lord Banbury's amendment.

Lord DAINESFORD asked the House not to allow Lord Dawson, on an occasion like that, to use the debate for the purpose of justifying the vivisection of stray dogs and introducing a totally irrelevant question into the discussion.

The EARL OF STRATHMORE said that the clause which Lord Banbury desired to eliminate was inserted after very careful consideration with various associations connected with the protection and care of dogs. He thought they would agree that the clause as it now stood gave a stray dog a better chance. The societies that discussed the question of this clause and agreed upon it were the Royal Society for the Prevention of Cruelty to Animals, the Canine Defence League, the Battersea Home for Lost Dogs, and the Glasgow Dogs Home. Up to the present no objection had been lodged at the Government department against this clause and therefore it was a surprise that this amendment should have been put down to eliminate it from the bill. It was the Government's view that the bill would be better as it stood.

Lord BANBURY said that though he was against dogs being vivisected he was not an antivivisectionist. He did not raise the question. If a noble lord wanted to buy a dog in a legitimate way the law allowed him to do so but it was another thing to say that if he (Lord Banbury) lost his dog it was to be a chance for some person who found it to keep it for a month and then sell it for vivisection.

The MARQUESS OF SALISBURY opposed the amendment. He said that if Lord Banbury had proposed to replace the clause with another which would have equally achieved his end and perhaps secured the particular view he held on vivisection that would have been a very different case but what he did was to vivisect from the bill one of its essential clauses without putting anything in its place.

The amendment to omit the clause was rejected by 33 votes to 5. The bill was read the third time and passed.

Industrial Accidents and Diseases

On July 11th the House of Commons discussed the estimate for the salaries and expenses of the Home Office, and Mr RHYS DAVIES moved a resolution of the vote

He spoke of the increase in accidents in the factories and work shops of the country. In 1927 there were 156,974, of which 973 proved fatal being increases of 17,011 and 165 over the accidents and fatalities recorded in 1926. He connected this increase with the inadequate number of inspectors employed by the Home Office. There was a substantial increase from year to year in the number of persons employed but although in 1914 there were 222 inspectors at the end of March 1928 the number was only 206. The number of female inspectors had remained almost stationary for seven or eight years. He asked for information about the working of the Act of 1926 which prohibited the use of white lead in interior painting. The figures relating to lead poisoning generally were alarming. The deaths in 1927 were reduced to 14 but the reported cases numbered 249, an increase of two over 1922. Forty cases of lead poisoning among house painters were reported in 1922, with 12 deaths but in 1927 there were 98 cases and 21 deaths. Had the Home Secretary sufficient inspectors to see that the Act of 1926 was carried out? What had become of the recommendations made by the committee appointed in 1921 to inquire into artificial humidity in textile and non-textile factories? He would like to know the figures for miners' nystagmus in 1927. In 1914 the new cases were 3,218, in 1926 they numbered 1,771 but the pits were stopped for seven months in that year. He understood that the Home Office was conducting an inquiry into silicosis among miners was not yet scheduled for workmen's compensation and some sufferers got no benefit from any source. He was pleased to say that the cases of anthrax coming under the purview of the Factories Department of the Home Office had fallen from 45 with 5 deaths in 1922 to 31 with 2 deaths in 1927. The Home Office recently appointed a committee to inquire into the cost of disinfecting East India wool but the Government disinfecting station at Liverpool had no control over the hudds and skins which had caused an outbreak at Bermondsey. He regretted that the report of the Factories Department for the preceding year was never ready in time for the discussion of this Vote in the House of Commons.

Mr HOLLINS said the process of getting an Order for any industry under the Silicosis Acts was very cumbersome and only a fraction of the total number of workers affected had been brought under a scheme since the first Act was introduced. Silicosis should be scheduled as an ordinary occupational disease. At present only organized bodies could apply for an Order and thousands of unorganized workers were beyond the scope of any possible inquiry. He pointed out also that if a worker had left a lead process for twelve months, or if the factory had given up the lead process for that period it was impossible for that worker to claim compensation. Sometimes persons showed symptoms of the lead poisoning several years after they had left the lead process. The period allowed for applications for compensation should be extended to three or five years. Mr Hollins contended that the present method of appointing certifying surgeons was not the best. Surgeons were not appointed because they were experts in the knowledge of lead poisoning or silicosis or anthrax. In the pottery industry they were paid one shilling for an examination with the consequence that twenty workers had passed before a certifying surgeon in as many minutes. Certifying surgeons should be whole-time men without private practice. This had been successful in the refractories industries scheme.

Mr MACRINDER said it was impossible for the present staff to inspect the factories and workshops in the West Riding of Yorkshire. In textile factories no adequate provision was made for the eating of meals. The only places where such provision was compulsory were those in which anthrax wools were handled. It was possible to disinfect such wools in the country of origin. The public was running a tremendous danger from the use of shaving brushes made of what was called Chinese hair or man hair, a material liable to be infected with anthrax. That hair was made into the cheapest imitation badger hair shaving brushes. The Departmental Committee on anthrax had proved that it was possible to have these brushes and materials disinfected and made safe.

Dr FREMANTLE supported the request of Mr Rhys Davies that the annual report of the chief inspector of factories should be issued in time for this debate each year. The figures of lead poisoning given in the report for 1926 were disconcerting. He objected to prohibition if it could be avoided. The methods of the Home Office inspector were those of the adviser and the friend who could help the employer to put things right. Already under the law the sanitary officers and medical officers of health did a certain amount of inspection and he urged that this should be considerably extended. Parliament would be on the wrong line in seeking to increase the centralized bureaucratic inspectorate. It should open up the factory inspection system to local people, who would gladly take an interest in it. Certifying factory surgeons ought to be given the opportunity of being more useful than they were at present. The suggestion of Mr Hollins that they should be whole-time men was impracticable. Welfare work in factories was extremely beneficent. Statutory welfare orders had been made for fourteen industries. Were they to be extended?

Mr JERKINS said the miners had appealed to the Home Office for years asking it to schedule silicosis as an industrial disease. The Home Office had done nothing since the introduction of machinery for boring though when boring was done in narrow working places the dust came back on the men and a large number particularly in South Wales were unable to work in consequence. No compensation was paid to them. The Home Office had instructed one medical man to inquire into silicosis in

the mining industry and other industries, and to report on cases. That was totally inadequate. A number of men who had worked where the dust came from the screening of coal had developed chest trouble from the dust they inhaled. Not one of these men was entitled to compensation. The Home Secretary should order that it be investigated.

Dr VEARON DAVIES speaking as an old certifying surgeon of over twenty years' experience in textile mills said the complaint against the small number of factory inspectors was justified. It was a physical impossibility for the inspectors adequately to inspect all the factories and workshops under their control. The Home Office had taken a retrograde step during the war in cancelling the reporting of accidents to certifying surgeons. Before the war the certifying surgeon had to visit the factory see the place where the accident occurred get a report from the injured person and get his or her report and finally to issue a report to the factory inspector and to the Home Office. That ensured that the mill managements reported the majority of their accidents because they never knew when news of an accident might leak out and get to the factory surgeon. The mill authorities knew that the factory doctor might be in the mill any day and it kept them up to the mark. The factory doctor was a sort of unofficial inspector and if he saw things which were not right he could say

'You must not do this or I shall have to report the matter to the factory inspector.' To save £7,000 a year the Home Office decided to do away with this reporting of accidents to the certifying surgeon and accidents were only reported to the factory inspector, who might live fifteen miles away. It was possible to report an accident so as to create a false impression and there might be many accidents which ought to be inspected by the factory inspector, but were not. Dr Davies recalled an instance in his own experience when by inquiring into an accident at a mill he had discovered that guards of a new type had been removed from every mule by the workers. Unfenced machinery was not always due to the fault of the employer. Dr Davies remarked that the figures for nystagmus were going up. In Belgium where there was not the same increase as in this country, compensation for nystagmus was only given for a definite time after which for some reason the cases improved. He drew an analogy with the old cases of 'railway spine' where after railway accidents people who got concussion of the spine never improved till the cases were settled by the railway companies. They were not malingering but some psychological condition prevented them getting better till their claim was paid. He wondered whether the giving of a lump sum by way of compensation for nystagmus might not have some effect on the recovery of the patient. The question of silicosis had been grossly neglected in this country. The mining industry had been run without the slightest medical supervision and children whom he had refused to certify as fit for work in the cotton mills had got work in the pits without any examination at all.

Sir VIVIAN HENDERSON intervening said that though the Home Office had power to make schemes in relation to silicosis in any industry the inspection of mines was a matter for the Mines Department. The question of allowing children to work in mines without examination was not a matter for the Home Office.

Dr DAVIES said silicosis by itself was not very dangerous. At the worst it caused shortness of breath and a little difficulty in breathing. The danger was contamination or infection with tubercle. That combination was extremely dangerous and fatal. Considering the risks miners ran from rock dust regulations should be made by the Home Office to deal with the problem. Certain people were more liable to infection by tubercle than others so in any scheme the health of the miner prior to and during his employment should be an important consideration. Examination of patients for silicosis should not be given to ordinary medical men but should be done by Home Office specialists because the disease was extremely difficult to diagnose accurately in the early stage. It was essential to have an expert radiographer and the Home Office should consider appointing a few specialists in silicosis to go round the country examining patients at different mines at regular periods. It was necessary not only to examine the mines where there was a large proportion of silica. Coal dust itself did not produce silicosis. It did good by lessening the liability to consumption. Colliers were less subject to pulmonary tuberculosis than any other grade of workers except agricultural workers. Apart from accidents the miners was a fairly healthy life.

Mr TAN SHAW praised the Home Office museum of safety appliances for machines. He thought that the Home Office could deal by administrative order with the practice known in Lancashire as shuttle-kissing. The trade unions could never get a body of medical opinion to say the practice was dangerous, but he associated it with the fact that nearly every weaver in Lancashire had badly decayed teeth or was wearing artificial teeth. Shuttle-kissing was a disgusting dirty and dangerous habit. If a weaver went off work with influenza the substitute who took the loom also quickly went off work with influenza. Sometimes three or four weavers used the same shuttle and went off work one after the other. It was impossible for the shuttle to remain clean. When bleeding colours were used in the yarn any weaver who used web of that kind had his lips teeth and inside of the mouth dyed. Years ago a committee on which Home Office representatives sat with representatives of the workers and of the employers had agreed that shuttles of the hand threaded type did exist and were practical. Since then the employers had retracted a little but at Colne one firm was issuing hand threaded shuttles with an artificial silk web.

Mr REGINALD SMITH spoke of the application of the 1927 silicosis scheme to the metal grinding industries. He understood the regulations debarred from benefit any men who after July 1st 1927 had been employed on a new process, however long before that

data they might have used the sandstone grindstone, and however neuro the silicosis from which they suffered. In the Sheffield district there had been a considerable removal of sandstone machinery about July 1st and a man whom the local doctor said was suffering from silicosis could not have a medical reference. The Home Office should make the regulation retrospective.

Mr CONNOLLY referred to draft regulations about to be issued by the Home Office in reference to the use of the oxy acetylene welding machine in ships and elsewhere. These regulations were based on the lessons of a fatal accident on the Mersey. They provided that prior to a welding operation by the oxy acetylene machine there must be a purifying of the air in the space where the machine was to work and also, during the operation, a continual supply of fresh air. He contended that the use of the machine in confined spaces should be totally prohibited, and nothing but an electric welder used. In nine cases out of ten a man would take the risk before losing the time required to get the air machine put on the job.

Sir VIVIAN HENDERSON, replying for the Home Office, said it was not fair to take the number of accidents in 1927 and compare them with the number in 1926. In 1925 there were 159,693 accidents of which 844 were fatal. In 1927 there were 156,974, of which 973 were fatal. He agreed that there had been a slight reduction of the factory inspection staff, and that the existing position was not satisfactory, but the inspection of factories had been more complete than in previous years. Any slackening had been in the inspection of small workshops, where there was not generally the same risk. The Factories Bill had been held up—he hoped only for the moment—but when it reached the Statute Book it would necessitate an increase in the Factory Department. The Home Secretary had promised to set up in the autumn a small committee on the staffing and organization of the factory inspectorate in the Home Office. Of this committee Sir Vivian hoped to be chairman. Dealing with points raised by previous speakers, Sir Vivian said that to prohibit the importation of a particular kind of shaving brush was already within the power of the Ministry of Health. Disease arising from the use of lead paint was hard to follow up by inspection, and the Home Office must rely to some extent on the industry itself. Both sides were co-operating in carrying out the regulations, and the position was improving. He had not the nystagmus figures for 1927. The Home Office was only concerned with nystagmus from the point of view of compensation. Prevention was a matter for the Mines Department. This was one of the unfortunate questions where they must get dual control. No satisfactory system of disinfecting hides for anthrax had been discovered but the Home Office would prosecute inquiries. The report on the further scheduling of wool was in the press but had not been published. It was extremely reassuring. He could not say what action the Home Secretary would take on it. Difficulties surrounded the question of silicosis and the time spent in inquiries before schemes could be framed had caused exasperation. The Home Secretary would consider whether he could expedite matters but to do so might involve legislation. He was inclined to agree with some of the strictures passed by Mr. Hollins on the work of certifying surgeons but to alter the whole system of certifying surgeons would need legislation. It was true that the certifying surgeon in normal circumstances was not competent to examine silicosis cases. A radiograph was also necessary, and the certifying surgeon had no power to get that, though the medical referee could. If they were to alter the certifying surgeon to a full-time medical expert on a definite salary they would require a Home Office medical staff or something of the kind and some compensation fund or medical fund into which employers would all pay. The possibility would have to be looked into and was being looked into at present in connexion with silicosis but he could not now come to a definite decision on it. The regulation about oxy acetylene welding to which Mr. Connolly had referred would have to be put into force or a further inquiry made into it.

The motion by Mr. Rhyds Davies to reduce the Vote for the salaries and expenses of the Home Office was then defeated by 212 to 110.

Voluntary Hospitals and the Rating Bill

On July 16th the House of Commons considered the Rating and Valuation (Apportionment) Bill as it had been amended in Committee. Mr. HARRIS moved a new clause to provide that the relief of rates offered to productive enterprises should be extended to hereditaments occupied and used as hospitals but not to hospitals run for private profit or gain. He said that during the last few years the strain on the voluntary system had been almost at breaking point. People were implored to give money to the voluntary hospitals and then it was handed back to the ratepayers in the form of taxation. Rates on the hospitals were tantamount to a tax on benevolence on the sick poor and on medical science.

Mr. CHAMBERLAIN said the bill was not a plan for deciding what kind of property might with advantage be relieved of rates. It was a special proposal which the Government were making for the stimulation of industry, and it was a far fetched suggestion indeed to attempt to bring hospitals within the definition of industry. Although he had expressed a certain sympathy in this matter he did not wish to be taken as in favour of any particular scheme for derating hospitals. If the question were to be considered they could not stop at hospitals. There were other kinds of property for which arguments on similar lines could be made and he did not wish to be taken as having accepted the principle as he had not given the question the necessary consideration. He recognized that there was a good case for the relief of the voluntary hospital and on some future occasion they might have some general scheme which would relieve

various classes of property which were rated to-day. In such a scheme the question of hospitals would properly find a place.

Sir H. CAULLEY pointed out that the assessment of the Sussex County Hospital had been put up tenfold.

Mr. T. WILLIAMS said the industrial depression and short time that was being worked made it a physical and financial impossibility for hospitals in necessitous areas to continue their work. The Minister of Health should consider the report of Lord Cave's Commission and Lord Onslow's Commission, and see what could be done.

Dr. VERNON DAVIES said that he would have been pleased if he could have accepted the arguments of the Opposition in favour of the amendment, but he could not persuade himself that the bill was on for the relief of voluntary hospitals. The argument had been used that hospitals might be regarded as productive in that they helped to produce medical men and nurses. Where was such an argument to stop? The hospital question at present was undoubtedly serious. He believed that the Minister of Health had that fact well before him and was anxious to deal with it. Attempts had been made to prove that breweries, which were to be relieved of rates, were a prolific cause of work for the hospitals. That might have been so in the past. In the old days it was not an uncommon thing to have patients in the hospitals as a result of alcoholic excess, but it was well known that there had been a great reduction in disease due to such excess. In his student days it was quite a common occurrence to come across cases of what were called 'beer drinker's heart' but at present they were the greatest rarities in clinical medicine. Cases of cirrhosis of the liver were also markedly decreasing.

Sir KINGSLEY WOOD in opposing the amendment said that the voluntary system so far as the hospitals were concerned was not fading away, but was firmly based. A great measure of the support came from the workers. So far as the rates on voluntary hospitals were concerned, the Central Valuation Committee had made valuable suggestions. If their advice was followed it would remove many difficulties.

The proposed clause was rejected by 219 votes to 110.

Foot-and-Mouth Disease

On July 16th the House of Lords again discussed the question of foot-and-mouth disease and the risk of infection from imported meat. The EARL OF STRATHMORE, replying to the debate, said that the Ministry of Agriculture was alive to the fact that infection could be brought in by blood, and the action taken against importation of carcasses from Europe was based on that fact. Experiments would be continued to find out, if possible, some way in which meat could be imported without any risk of infection.

In the House of Commons, on July 16th Mr. GUINNESS in reply to Sir R. Thomas, said he was having inquiries made into an alleged cure and preventive for foot-and-mouth disease, consisting of a herbal preparation administered to animals by mixture with their fodder which was said to have been discovered by a Dutch experimenter.

Poison Gas in Warfare

Lord DANKSFORT opened a debate in the House of Lords on July 11th, on the use of poisonous gas in warfare. Lord HALDANE remarked that the total amount of phosgene gas required to produce a lethal atmosphere up to forty feet in London from Chalk Farm to Clapham Common and the Docks was under 2,000 tons a quantity which could be carried by enemy aircraft at the present time. Phosgene gas itself was out of date. The more modern gases whose base was arsenic could be brought over in a liquid form and blown into a fine smoke by a small amount of high explosive. Forty tons of such a new gas would suffice instead of 2,000 tons of phosgene. Intense mental distress accompanied the symptoms of poisoning by these severe gases. Men had been known to act as though driven mad by their pain and misery. Chemical dye plants could be switched over very readily to produce these gases in large quantities. Within a week three large chemical firms in Germany could make 100 tons a day. Lord RAYLEIGH said mustard gas was still perhaps the most deadly of the purely gaseous substances which could be used for an attack on London. To produce it was simple, and prohibitive regulations would be simple. Preparations should be made in case of need for the evacuation of London and something should be done to make gas-proof the buildings needed for administration. Arsenical gases were not gases in the true sense of the word, but finely divided smoke consisting of solid particles. Sir Oliver Lodge and his assistants had shown that such particles could be rapidly aggregated by suspending highly electrified conductors in the air to be cleared. It might also be possible to suck away such gases through the London sewers. Lord SALISBURY said the horrors depicted in the debate were not without foundation and there was also the danger of panic. The last word of science had not been said on defence and many methods to mitigate the severity of an attack though discovered had not yet been dealt with.

Bill to Amend the Coroners Act

In the House of Commons on July 11th, Mr. HOPKIN MORRIS introduced a bill to amend Section 4 (3) of the Coroners Act 1887. This section indicates that a coroner's jury has to inquire who the deceased was, how and where he came by his death, and if he died by murder or manslaughter, the persons, if any, whom the jury find to have been guilty of such murder or manslaughter. Mr. Morris's bill proposed to cut out that part of the subsection relating to the naming of the person found guilty of manslaughter. The bill which was backed by Dr. Vernon Davies, was read a first time.

Child Destruction Bill

On July 12th the House of Lords took the Report stage of the Child Destruction Bill (formerly the Infanticide Bill). On the motion of Lord DARLING a subsection was remodelled to read:

For the purposes of this Act evidence that a woman had at any material time been pregnant for a period of twenty-eight weeks or more shall be prima facie proof that she was at that time pregnant of a child capable of being born alive. Other drafting amendments were also made. The bill was read a third time on July 16th and sent to the Commons.

Medical Treatment of War Pensioners.—On July 12th Mr CAMPBELL STEPHEN asked what remedy on ex-service men had when he was recommended by the Ministry of Pensions for treatment at home by his panel doctor but the panel doctor certified that treatment by the Ministry was necessary. Major TRYON said the case would fall to be dealt with under the ordinary arrangements available to insured persons under the National Health Insurance Acts. The Ministry could not accept the doctrine that the panel doctor should decide for them and if the man had a grievance against the panel doctor the normal course would be for him to make an application to the Insurance Committee. Mr CAMPBELL STEPHEN asked whether if the man considered the advice of his panel doctor was right, there was a medical referee whose opinion the Ministry and the panel doctor could accept, or whether the Minister would set up such a referee. Major TRYON said he could not set up a referee. The case would be considered by the doctors of the Ministry of Pensions whose opinions must decide the action to be taken by the Ministry. Major TRYON denied, on July 12th that pensioners encountered difficulty in obtaining treatment owing to the reduction in the number of war pensions offices. The waiting period for admission to hospital had actually been reduced.

Small pox.—Mr GROVES, in a question to Mr Chamberlain on July 12th, asserted that the cases of small pox occurring in London were so mild as to be hardly distinguishable from chicken pox and that certain medical men believed these cases were not small pox but alastrum or a new disease. Mr CHAMBERLAIN replied that the small pox now prevalent in this country should not be confused with chicken pox or some new disease. Mr GROVES asked whether the Minister would issue fresh regulations permitting medical officers of health to leave the cases in their own homes, instead of having them removed to the small pox hospital. Mr CHAMBERLAIN answered that, in view of the risks to the public health which would be involved by further spread of the disease he was not prepared to countenance the course suggested by Mr Groves.

Death Certification.—On July 11th Sir KINGSLEY WOOD told Mr Naylor that Mr Chamberlain had seen a report of observations by Dr F J Waldo senior coroner for London concerning the importance of not permitting burial or cremation until the certifying doctor had seen and examined the body. These observations, Sir Kingsley said appeared to pay no regard to the practical considerations involved, and to ignore the fact that, with regard to cremation, the safeguards recommended and others more stringent had long been compulsory. The whole subject had been discussed during the passage of the Births and Deaths Registration Act 1926, and Mr Chamberlain was not prepared to introduce further legislation.

Notes in Brief

The number of metropolitan police magistrates is to be brought up to the statutory maximum of 27 instead of 25 the present number. An authoritative inquiry will be instituted this autumn into the whole work and organization of the metropolitan police courts.

One of the medical inspectors of the Ministry of Education has been specially charged with the inspection of nursery schools under the direction of the chief medical officer.

The Minister of Health states that substances sold as ice-cream sometimes contain the ingredients of which synthetic cream is composed. Local authorities generally have considered that they could not with advantage take any steps to prevent this practice since there is at present no statutory definition of ice-cream.

The Ministry of Agriculture has decided not to build a quarantine station at Glasgow until experience has been obtained of the extent to which the London quarantine station is utilized.

The Minister of Health is not aware of the need for the issue of any special regulations by which medical officers wholly employed by or resident in, a Poor Law union would be required to inspect casuals on the evening of their arrival in an institution.

Sir Kingsley Wood states that officers of the Ministry of Health when inspecting casual wards will give special attention to the washing arrangements for casuals.

No experiments in wireless communication between the island of Foula and the mainland for medical purposes have yet been made.

Universities and Colleges

UNIVERSITY OF OXFORD

F HAWKING University College has been elected to the Theodore Williams Scholarship in Pathology for the year 1928-29.

The following candidates have been approved at the examination indicated.

FINAL B.M. B.Ch.—O A Beadle M V Bhaskar W H Brown T L Davies E R Holdway A J Leslie-Spinks A J M Melly A E. Porritt L T Ride, H G Wells Florence H Johnson, Alice D K Peters *Forensic Medicine and Hygiene* M V Bhaskar G Campbell, B R Caygill, R M J Harper E R Holdway F G Parker H G Pritchard C R Salkeld D C Shields

Florence H Johnson Carolino E MacNolee Alice D K Peters, Joyce Wright *Lithology* A D C Bell T M Gledhill R D Harding H O Harley E Harvey F Hawking E R Holdway K A Irvine J M Lees A W D Leshman J C Nicholwood N C Parfit A B Stokes R L H Townsend W B Williams Ruth Sandeman *Material Medica* H J B Aldous E W Brown N P Bruce T M Davis R D Harding H Hunt J I Jealins C J King Turner J C Leadham Greco A W D Leshman R O MacNolee J N O'Reilly R S B Pearson B T Squire, A B Stokes W S Tegner H A Trouble H C Wadge Olive M. UNIVERSITY OF LONDON

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

THE Goldsmith Entrance Examinations have been awarded to E S Harverton and A L Jacobs.

UNIVERSITY OF MANCHESTER

DR. G H H BOOTH has been appointed Demonstrator in Anatomy.

QUEEN'S UNIVERSITY BELFAST

DR. E B C MAHES has been appointed to the Chair of Pharmacology and Therapeutics and Dr F M Allen Lecturer in Materia Medica and Therapeutics.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A QUARTERLY Council meeting was held on July 12th when the President, Sir Berkeley Moynihan Bt was in the chair.

Council Election

The President announced the re-election of Mr F J Steward and the election of Mr R E Kelly (Liverpool) Mr R G Hogarth (Nottingham), and Mr L P Gamgee (Birmingham) as members of the Council. Mr Gamgee becomes substitute member for Mr Thelwall Thomas until 1935. The new members were introduced and took their seats in the Council.

Professors and Lecturers

The following were elected professors and lecturers for the ensuing year.

Histological Professors.—Sir Arthur Keith (six lectures on the anatomy of the human body) A H Evans O.B.F. (one lecture on developmental ontogenetic cysts and diverticula) G E Gask C.M.G. D.S.O. (one lecture on radium in the treatment of malignant disease) O A Fennell (one lecture on local anaesthetics) R J McN Lyle (one lecture on the treatment of acute abdominal disorders) C P G Wakeley (one lecture on the etiology pathology and treatment of sarcomas of the intestinal tract) R T L Mayo (one lecture on the treatment of varicose veins and varicose ulcers by injection).

Arts and Gale Lecturer.—H A Harris (three lectures on the growth of the long bones in health and disease). *Erasmus Wilson Lectureship*.—T W P Lawrence and C E Shattock (three demonstrations each on the pathological contents of the Museum). *Arnott Demonstrations*.—Sir Arthur Keith (six demonstrations on the contents of the Museum).

Honorary Fellows

Dr Regand (Paris) and Sir George Newman were elected honorary fellows.

Election of Officers

Sir Berkeley Moynihan was re-elected President and Mr Hey Groves and Mr Warren Low were elected Vice-Presidents for the ensuing year. Mr R. H. Burne was re-elected physiological narrator, Mr C F Beadles was re-elected pathological narrator and Sir Frank Colyer was re-elected honorary narrator of the oedontological collection for the ensuing year.

Diplomas

The diploma of Fellowship was granted to J O B Allen. The diplomas of Membership were granted to Nellie Brown and H J Nimbalker.

The following diplomas were conferred jointly with the Royal College of Physicians of London.

Laryngology and Otology.—J Acorn N Attygnille H K Baan, N E H Box, C H Carroll, G D Mallontra T G Millar, A A Miller G W Morey, W J Robertson E M Steel, D B Sniton M R Wadia.

Psychological Medicine.—Norah A. Haworth R Levinson, Agnes M Macgown J J B Martin A Pool G M Tothill.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the examination concluded on June 15th 50 candidates were approved and 108 rejected.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly business meeting of the College held on July 6th, the President duly admitted as Licentiates in Medicine and Midwifery the following candidates who had passed the Conjoint Final Examination of the Royal Colleges of Physicians and Surgeons Ireland.

T B Creamer Eliseo Cusseo, M Duophy R A Forde J Gaughan W G Greene A E Lee, J L Maslin S O Matlock F J A Murray H Robinson.

Medical News.

DR CHARLES FRANCIS WHITE of the Ministry of Health and formerly assistant port medical officer for Liverpool has been appointed medical officer of health for the Port of London in succession to Dr W M Willoughby, who is now medical officer of health for the City of London.

An afternoon reception will be held at Brockley Hill, Stanmore, the country branch of the Royal National Orthopaedic Hospital, to day, Friday, July 20th. H R H the Duke of Gloucester, President of the Hospital, hopes to be present.

The Fellowship of Medicine and Post Graduate Medical Association announces that a special course will begin at the Hospital for Consumption and Diseases of the Chest, Brompton Road, on July 30th occupying from 10 a.m. to 4 p.m. daily for a week, including Saturday. From August 8th to September 1st a special course will be undertaken by the staff of the All Saints' Hospital for Genito-Urinary Diseases. Dr Eric Pritchard will hold an afternoon course at the Infants Hospital from August 13th to 25th. From August 27th to September 8th an all day "brush up" course will be held at the Queen Mary's Hospital, Stratford, E 15, consisting of demonstrations in medicine, surgery, and the specialties. Courses in September will include the following: medicine, surgery, and the specialties, at the Westminster Hospital, diseases of children, at the Queen's Hospital, electrotherapy, at the Royal Free Hospital, ophthalmology, at the Royal Eye Hospital, psychological medicine, at the Bethlem Royal Hospital, orthopaedics, at the Royal National Orthopaedic Hospital. Copies of syllabuses and information regarding the general course which is continuous throughout the year, and may be taken for varying periods from one week upwards, may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W 1.

A REUNION dinner of the Lausanne Medical Graduates Association was held at the Langham Hotel, on June 14th. Dr E E L Burnier of Cliftonville, Margate, was elected president of the association. It was announced that the following British medical men have recently been approved by the University of Lausanne for the M.D. degree: Major A. N. Bose, I.M.S., G. Elliot, P. E. M. Lanier, and J. J. F. Souza.

The late Viscount Hambledon, who died on June 16th, had been a member of the Council of King Edward's Hospital Fund since 1921, and of its Revenue Committee since 1923. He was a member of the Ambulance Cases Disposal Committee from 1923 to 1924, and chairman of the Pay Beds Committee in 1927-28. He was also chairman of King's College Hospital, and took an active interest in the British Hospitals Association, and in the raising of money generally for London hospitals. The Management Committee of the King's Fund has adopted a resolution recording its appreciation of Lord Hambledon's great services to the voluntary hospital system and its sorrow at his death.

The Marchioness of Titchfield, chairman of the special appeal of the National Association for the Prevention of Tuberculosis, announced at a luncheon on July 17th that an anonymous donation of £50,000 had been received, bringing the total sum raised by the appeal to £110,568.

The annual report of the Papworth Village Settlement for the year ending December 31st, 1927, has been published, and contains a fully illustrated description of the various activities at this institution. We referred on June 30th (p. 1115) to the opening by the Prince of Wales of the Clifford Alibon memorial cottages in the settlement.

The name of the Highfield Sanatorium, at Edge Lane Drive, Liverpool, has been changed to Broadgreen Sanatorium.

The late Sir William Church, Bt., President of the Royal College of Physicians in 1893-1905, who died in April last, has left estate of the value of £52,493, with net personalty £51,623. He bequeathed £1,000 to the Royal Society of Medicine and £100 to Epsom College.

The second medical study tour in Czechoslovakia organized by a French agency on the invitation of the spas of the former country, will take place in September, the programme occupying ten days and including visits to Frauenthal, Marienbad, Carlsbad, Prague and Brno where a health exhibition will be in progress. The tour will commence at the frontier station of Cheb on the afternoon of September 8th and will terminate in Austria, at Vienna on September 17th. The inclusive cost between these points, with first-class travel, hotels and meals, excursions, etc. will be 1,500 French francs (about £12) a head. At the spas the members of the party will be officially entertained and conducted on visits to the bathing establishments. Information may be obtained from the agency, "Mon Voyage, 9 rue de la Michodière, Paris 2°.

The following papers, among others, will be read at the International Congress against Alcoholism, to be held at Antwerp from August 20th to the 25th. The alcohol question and social hygiene, by Sir Arthur Newsholme; the concentration of alcohol in the blood and the diagnosis of drunkenness, by Professor Firket of Liege, latest experiments on alcohol and heredity by Professor Laitinen of Helsingfors; changes in the endocrine glands in the descendants of alcoholics, by Dr Pannsepp of Tartu; the results of American prohibition from the hygienic aspect, by Professor Haver Lemstra of New York; alcoholism in Russia, by Dr Dahlgren of Malmö; alcohol and sport, by Dr Saleeby; and the organization of welfare centres for drinkers, by Professor Ganser of Berlin and Dr Revillid Masaryk of Geneva. Further information can be obtained from the general secretary, Professor Charles Verlat, 10, Rue Van Dyck, Antwerp.

The eighth congress of the Society for the Study of the Physiology and Pathology of Digestion will be held at Amsterdam from September 12th to 14th.

A POST GRADUATE course in recent advances of medicine will be held in Vienna, from September 24th to October 6th, and will be followed by practical classes during the subsequent week. Further information may be obtained from the dean, Dr Leopold Arzt, The University, Ring des 12 November, Vienna, I.

PROFESSOR SIGALAS has been re-elected dean of the Bordeaux faculty of medicine.

DR HANS THIERFELDER, professor of physiological chemistry at Tübingen, has recently celebrated his 70th birthday.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSLUM 9561 5562 9563**, and **2563** (internal exchange four lines).

THE TELEGRAPHIC ADDRESSES are

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Facillus Dublin* telephone 62550 Dublin), and of the Scottish Office, 7 Drumshough Gardens, Edinburgh (telegrams *Associate, Edinburgh* telephone 24361 Edinburgh).

QUERIES AND ANSWERS

HAEMOPHILIA AND DENTAL EXTRACTION

"A P A" asks for information regarding the best method of preparing a young man suffering from haemophilia and had oral sepsis for dental extractions.

FINGER SUCKING

DR J H BACOCK (London) writes in reply to "S C N" (July 7th p. 39). A child who sucks its finger or thumb usually sucks something with the other hand at the same time often a blanket or a woollen* sometimes its hair always something soft and warm. Sometimes the disengaged fingers of the same hand are used but this is rare. Stopping this correlated habit often easily accomplished—for example by taking away the woollen*—will often force the finger sucking, in older children I have no experience of babies but give the hint for what it may be worth.

INCOME TAX

Replacement of Car

"N J" bought a car in 1923 for £270 and sold it in June 1927 for £75 buying a different make and type of car for £255. His claim to treat the out of pocket expense of £100 as a replacement is

refused, the Inspector of Taxes holding the view that as a *similar* make and type of car could have been bought for £163 in 1927, the 'replacement' cost is £85 and the remaining £105 represents improvement and is therefore capital outlay.

It is difficult to refute the official view because improvement is the characteristic of capital, as distinct from allowable expenditure. Further it must be admitted that when the cost of cars were rising the revenue authorities were consistent, and practitioners were not infrequently allowed to deduct the full cost of replacement though the cost of the new car was substantially greater than the cost of the old one. The depreciation allowance pays in the long run in practically every case—which is why the extension of that allowance to professions was urged on the Royal Commission by the British Medical Association some years ago, and why it has been consistently advocated in those columns. It is to be regretted that "N J" did not put himself on that basis two or three years ago.

"W E" held a full time appointment and owned a car run at his own expense. He then entered on private practice sold the car for £75, and bought a new one for £245. Can he claim £170 as the cost of replacement?

In the circumstances it seems impossible to contend successfully that the £170 was expended in the working of the practice. Either it was capital outlay for the practice or represented delayed expenditure applicable to the appointment. The best "W E" can hope for is a depreciation allowance of 20 per cent of £245—that is, £49.

Decoration of Consulting Room

"E M A" started consulting practice two years ago and took over a house from another doctor having to spend a certain amount upon redecoration of the waiting room and consulting room. Is that expenditure deductible, or is it capital outlay?

On the assumption that the rooms in question had been used for similar purposes by the previous practitioner and that there was no appreciable improvement or alteration in the rooms as compared with their previous condition—that is, when the former decorations were new—we consider the expense was allowable. But there is no legal right to have it regarded as expenditure of any year but the year in which it was incurred.

Change of Practice

"A G N" left his former practice on May 14th last and has taken another practice in a different part of the country. He has been informed by the authorities that for 1928-29 he will be assessable on the actual profits of that year and that the assessment for 1927-28 will be revised to the actual income of that year.

The official view is apparently correct. The matter was dealt with in a note on page 1037 of our issue of June 16th last in which the effect of the legislative changes was explained. We suggest that our correspondent refer to that note and, if necessary, write to us again on any specific point of difficulty.

Receipts after Retirement

"SENEX" retired, owing to ill health, at the end of the last partnership year December 31st 1927. Is he liable to return no income arising subsequently received by him for his share of the partnership income?

No. It has to be assumed that during the continuance of the partnership the cash receipts approximated to the true gross earnings. "Senex" has paid tax on the income up to December 31st, 1927 and anything he may now receive is merely a belated payment to him of income which has already been taxed. Whether the partnership in its early years paid tax on more than its own net cash income we do not know—the authorities are apparently prepared to assume that it did, and no doubt will see that the cash basis is not applied to the early years of the new firm.

LETTERS, NOTES, ETC.

ARTERY FORCEPS AND LIGATURE CARRIER

MR. N. I. SPURGES, F.R.C.S. (Leicester) referring to the description by Mr. E. Milne Eaton of an artery forceps and ligature carrier for deeply placed vessels on July 7th (p. 19) writes: I designed an instrument for similar work several years ago which was described in the *Lancet* of January 18th 1913. I have a model of the instrument, but it was never manufactured in bulk owing to financial considerations. Its use was demonstrated by me at a meeting of the Midland Obstetrical and Gynaecological Association at Leicester.

SEA SICKNESS

"TERRA FIRMA" writes: It is difficult for one who has suffered severely from this onsets to accept any but a labyrinthine explanation of it. After all sea-sickness is one of a group and the similarity of the effects of trains, cars, swings, roundabouts, and even the old fashioned waltz, is too striking to have anything

but a common cause. Once in childhood, I drove a bus and an interurban in disorder from a railway carriage. The trick of twisting a swing and allowing it to twist rapidly with myself in the seat produced a similar effect upon me which is difficult to explain on any abdominal hypothesis. In the Physiological Laboratory at Cambridge I was induced to test the effects of rapid rotation of the vertical body with the head in a erect, stooping, and on the shoulder. The demonstration of the part played by the semicircular canals was convincing to most, at least, and my subsequent apparent rotation in three planes simultaneously led to prostration for the rest of the day with all the symptoms of *mal de mer*. Experiments during many crossings of all the seas round Britain have convinced me that no diet in reason, has any effect upon the disability. The weakness is hereditary, and I have tried, without success to prevent car sickness in my own children by liberal doses of glucose. In my experience children under 2 years of age are nearly immune, the disability increases from that age to adolescence and afterwards diminishes. In 1918-19 I circumnavigated Africa without being actually sea sick. The advantage of the supine position is certain whatever may be the explanation, the nausea appears to be secondary to the vomiting as in hyperemesis gravidarum. For short crossings I recommend nerve depressants such as the bromides chloral and alcohol, for a long voyage rest on the bank until the sufferer is accustomed to the motion or the sea moderates.

MR. GORDON D. KNOX (London) writes: The comments you have published on sea sickness upholden me to give a personal experience. I can describe myself as a fair sailor, the type who is liable to be ill at the beginning of the season and who is then immune during reasonable weather. I made by accident what to me was the astonishing discovery that even after the feeling of nausea had begun it could be staved off and even prevented by smoking a pipe or cigarette and smoking pipe after pipe or cigarette after cigarette. Greatly daring I recommended my tentant to a colleague who complained that he had never crossed the Channel without being sea sick. Thoroughly sceptical he tried my plan and made his first passage over in comfort. I recognize the danger of attempting to generalize on two cases but should like very much to know if there is medical evidence to justify my belief that with the habitual smoker smoking may stave off sea sickness.

MUSCULO SPIRAL PARALYSIS AFTER QUININE INJECTIONS.

DR. J. I. KUIT (Piet Retief, Transvaal) writes: I read in the *Epitome* for April 28th (para 407) a reference to musculo-spiral paralysis following the injection of quinine for malaria. Towards the end of February last I had a bad attack of malaria. I was treated by a colleague, who ordered three daily injections of 10 grains of quinine dihydrochloride. This was continued for about five or six days. The injections were subcutaneous and at my own request were given over the deltoid muscle after antiseptic rub and left. After the second day the injections were absolutely painless as a matter of fact, the whole area from the point of the shoulder to the middle of the upper arm on both sides became completely anaesthetic. This has gradually worn off and for the last fortnight the sensation has been normal. When first I left the nursing home fourteen days after the first injection, I could not hold a pen to write and both arms were very weak. It was nearly three weeks before my arms felt in any way normal. That there must be some disturbance of the trophic nerves in my case is indicated by the fact that small pustules keep appearing on both upper arms, and these are limited to the area that was anaesthetic.

HOLIDAYS FOR FACTORY GIRLS

WE have received the following letter signed, on behalf of the Factory Girls Country Holiday Fund by the Countess of Sandwich, Dame Mary Scherfield, Miss Lillian Bratton, the Bishop of London, and Mr. J. F. Green:

"Will you once again give us the opportunity of drawing the attention of your readers to the Factory Girls' Country Holiday Fund which may well claim to render good service to our poorer sisters, and so, to the whole community. The change wrought in these pale Londoners in a few days is almost incredible save to the eye witness. Good food and plenty of it rest on the beach, or in the fresh country fields and above all, freedom from care—knowing their holiday is paid for before they go—work wonders. There are now hundreds of girls hoping to be sent away during the next few weeks. Fresh applications come in daily, but we have not enough funds to send half the number at present. Many of the applicants have been saving out of their earnings week by week since the beginning of the year towards their share of the cost of their holiday. This fund helps chiefly the poorest class of factory workers, most of them are the main support too of their families. Subscriptions and donations will be thankfully received and acknowledged by the honorary treasurer, Mrs. Slater, or by Miss Canney, 75, Lambeth Conduit Street, London, W.C.1.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 45, 46, 47, 50, and 51 of our advertisement columns and advertisements as to partnerships, assistantships, and locum tenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 24.

British Medical Association.

NINETY-SIXTH ANNUAL MEETING, CARDIFF, 1928.

President's Address

OS

SOME REACTIONS AND A RETROSPECT

BY

SIR EWEN MACLEAN, M.D., F.R.C.P., Hon. F.A.C.S., F.R.S.E.,
PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE

MR LORD MAYOR, LADIES, AND GENTLEMEN,—I profoundly appreciate the great honour of being asked by my colleagues and by the authorities of the British Medical Association to occupy the Presidential Chair for this year.

Having regard to its outstanding achievements in the past, its present status and power, and its future of ever-increasing authority and responsibility, to be the titular head of this great Association for the allotted span must surely evoke the humility and gratify the ambition of any man.

The Annual Meeting of the Association last assembled in Cardiff in 1885—forty-three years ago. Queen Victoria was the reigning sovereign, and amongst the local historic events of the year was the transit of the first train through the Severn tunnel. Dr W. T. Edwards, whose skill as a physician and whose high character and public service are gratefully remembered, was the President, Dr Alfred Sheen, a very distinguished practitioner, was the General Secretary, and Dr Thomas Wallace, J.P., who is with us to-day, was an active member of the local executive. Dr Donald Paterson, whose articles in the *Journal* on Cardiff and its surroundings have been so much appreciated, was a young house-surgeon at the Infirmary, and already giving promise of his very distinguished career. At that Meeting, as now, the public, the Corporation, and other bodies of Cardiff placed every available facility at the disposal of the Association for the scientific work and the social relaxation of its members.

I take this opportunity, on behalf of my colleagues and myself, to offer our grateful thanks to the Lord Mayor and Corporation, to the President, Principal, and Council of the University College, and to the President and Council of the Welsh National Museum, for so generously giving us the use of their magnificent buildings in the Cathays Park for the Sections, receptions, and administrative requirements. We also much appreciate the generous interest taken in our Meeting by the Marquess and Marchioness of Bute, as by the Marquess and Marchioness of forty years ago.

PUBLIC WORK OF THE ASSOCIATION

Since 1885 Cardiff has so multiplied its population that it is now two and a half times as great as it was then, and the city has achieved the rank of one of the foremost ports of the world, whilst the Association has trebled its membership to nearly 34,000, and manifolded the degree and range of its power. To-day the British overseas membership of the Association alone is nearly equal to the total membership in 1885.

It is alleged at times, in criticism of the activities of the Association, that its great power is expended predominantly in the personal interest of its members. This is very far from being the fact. It is certainly true that the Association has achieved a great deal in its endeavours to raise the status and improve the conditions of service of medical men and women, whether in the public health service, in the combatant services, in work under the National Health Insurance Acts, in the Colonial Medical Service, or in general practice. But, leaving all this aside, from its foundation the Association has been concerned

chiefly with the maintenance of the professional standard of education and conduct, both pre- and post-graduate, the promotion of scientific research, and the development of a national public health policy which will allow the profession to make its maximum contribution to the well-being of the community.

Inasmuch as the British Medical Association represents the medical profession as an organized body, it is clear that its corresponding sphere of action lies rather with public bodies than with individuals. In seeking to inform the public as to the principles underlying a sound public health policy, the Association's appeal is primarily to the responsible Government of the day, to members of Parliament, to the departments of State, to local authorities, and to the numerous voluntary bodies, whether lay or professional, through which public opinion is formed.

The general scope of the Association's activities in this connexion, and the nature of its influence, may be illustrated by the list of the Royal Commissions, Departmental Committees, etc., to which the Association has submitted evidence on matters not principally affecting the economic interests of the profession: the Government Committees on which the Association has been represented and the publications of the Association.

As early as 1868 the creation of a department of State to deal with specifically public health matters was urged upon the Government and eventually in 1919 the Ministry of Health was formed. By the influence it exercised and by the atmosphere it created the Association was largely instrumental in the setting up of this separate department of State.

It was shortly after the Cardiff Meeting in 1885 that the Association promoted and financed an investigation into the health of 100,000 school children, and was largely responsible for the creation of the School Medical Service. The compulsory examination and treatment of school children has always been a feature of the Association's policy, and from 1905 repeated attempts were made to embody this principle in legislation. Until 1907 these efforts were unsuccessful, but under the Education Act of that year the School Medical Service was established.

The action taken by the Association in connexion with maternity and child welfare has been largely concerned with raising the general standard of midwifery and with proposing amendments (often accepted) in the rules of the Central Midwives Board—amendments directed towards prevention of maternal and infant mortality. During 1908-9 evidence was prepared for submission to the Departmental Committee on the Midwives Act, 1902, and the recommendations of that committee included many of the reforms suggested by the Association. Special inquiries have been conducted into the important subject of ophthalmia neonatorum (1907-9), the value of maternity and child welfare in relation to the reduction of infant mortality (1920), cardiac disease in children (1923-27), and puerperal morbidity and mortality (1924-27).

A typical example of the Association's work for the promotion of maternity and child welfare is afforded by the story of its action in connexion with ophthalmia neonatorum. In 1906 this was the subject chosen by the Council for the Middlemore Prize. In 1907 the same subject was

chosen for discussion in the Section of Ophthalmology at the Annual Meeting of the Association, and on the recommendation of this Section the Council appointed a committee to consider the question of prevention of the disease. The committee reported in 1908, and by 1910 public opinion, stimulated by the publicity given it by the Association throughout this period by the means already mentioned and by repeated reference in its *Journal*, had brought about the adoption of notification by a considerable number of authorities. In 1910 the Council issued a model scheme for administration in areas where notification had been adopted, and this was circulated to the Divisions of the Association. In 1914 the notification was made compulsory by statutory Order, and the general policy of the Association with regard to notification and treatment is now part of the health policy of the nation.

In 1914 the Association gave evidence before the Royal Commission on Venereal Diseases, and in many important respects the recommendations of the Association were incorporated in the report of the Royal Commission.

The Association has from time to time endeavoured to secure the elimination of defects from the Law of Lunacy and Mental Deficiency by means of (a) preparation and submission of evidence to Royal Commissions and other official bodies, and (b) appointment of special committees to consider and report on the lunacy law as a whole or on various aspects of it.

The interest of the Association in the care and control of mental defectives has been long and continued. In many instances reforms urged by the Association have been embodied in legislation or in recommendations of Government bodies appointed to consider the whole question. For example, amendments were successfully introduced into the Lunacy Amendment Act of 1890, and the Defective and Epileptic Children Act, 1899 (to provide special instruction for mentally deficient children). The Association also, in 1909, urged on the Home Secretary the need for giving full effect to the report of the Royal Commission on the Care and Control of the Feeble-minded. In 1911 a memorandum on the policy of the British Medical Association as regards amendment of the lunacy laws and care and control of the feeble-minded was forwarded to the Home Secretary. The Mental Deficiency Bill, which was introduced by the Government in the following year, and which eventually became law in 1913, was in general conformity with this policy.

With regard to the work of the Association in connexion with the standard of therapeutic substances and appliances, this has been directed towards (1) the improvement of the *British Pharmacopoeia*, (2) the adequate standardization of therapeutic substances, (3) the protection of the public from the abuse of "dangerous drugs," drugs of addiction generally, and alcohol, (4) the protection of the public from the exploitation of fraudulent and harmful proprietary remedies (so-called patent medicines or secret remedies), and (5) the prohibition of improper and misleading advertisements of proprietary remedies.

Since 1906 the Association has given evidence on thirty Royal Commissions and Departmental and Governmental Committees, excluding those which required evidence bearing mainly on the pecuniary interest of the profession.

In regard to the education of the public in health matters, the Association has always played its part in directing the attention of the public to questions of hygiene, mainly by representations addressed to central and local health authorities and to members of Parliament, but also on occasion by publications and addresses intended for the general public. It has also from time to time urged upon its members the necessity of individual efforts in this direction.

With regard to the Council's future proposals connected with the problem of the public education in health, a memorandum issued by the Association indicates the action which can be taken by Divisions and Branches in assisting in the education of the public in health matters.

The foregoing, though but a short and incomplete review of its wider activities, goes far to answer the criticism referred to and to indicate the breadth of view which the Association takes of its obligations and responsibilities.

In two data, amongst others, in the history of the

Association, the South Wales and Monmouthshire Branch can claim especial interest. In the year 1877 the first Gold Medal of the Association was awarded to Dr Henry Naunton Davies for conspicuous bravery and skill in connexion with the Tynewydd Colliery disaster, and we are glad to have with us to-day, as an active member, one of his surviving sons.

Then, again, that most significant event, the birth of the Representative Body, took place at the Swansea Meeting in 1903, and the proceedings of the past few days go to show that the Representative Body, now a quarter of a century old, has much to its credit and is dealing wisely and thoroughly with problems arising within the profession, and with those questions, ever increasing in number, which by successive Governments and by the public "stand referred" to the Association.

ANCIENT CYMRIC MEDICINE

Casting back to more distant times, the exhibit which, by the courtesy of the authorities, has been set up in the Library of the National Museum shows, I think, that "Ancient Cymric" medicine affords a most attractive field for study and research, and I am indebted to my friend Dr Roland Williams for many interesting observations and gleanings in this connexion.

Handed down from very remote times, a glimmering of medical science would seem to have existed in pre-Celtic and Celtic Britain. It is difficult to conceive, for instance, that the New Stone Age and the Bronze Age, rich as they were in the pioneer achievements of civilization, should have been lacking entirely in some form of indigenous medical lore. Possibly, too, those very early traders from the older Mediterranean civilizations who came to seek tin from Cornwall left behind them something of the healing traditions of other lands. At any rate, however such knowledge may have accrued, there are some grounds for crediting the Druids with perhaps a greater preoccupation with medicine than was usual in a primitive priestcraft. The Greek geographer Strabo (born about 60 B.C.) has left it on record that the soothsayers are sacrificers and physiologists, the Druids, in addition to physiology, practise ethio philosophy. Pliny gave a brief account of a Druidic *Materia Medica* in which the mistletoe or "All-Heal" was held in highest esteem. Presumably, too, the British Druids were similar in type to the Druids of Gaul, to whose advanced "knowledge of the Laws of Nature" Cicero referred. It is interesting to note that, as preventives to ill health, the Druids prescribed cheerfulness, temperance, exercise, and early rising, qualities and practices which—shall we say?—have remained characteristics of the Cymry to the present day. Albert, another of the Druidical maxims, asserting that "Money lent in this world will be repaid in the next," would not, I fear, in practice to-day, rank as a gilt-edged security.

After the Druids came the Romans. Soldiers, engineers, administrators as they were in the main, we do not know what legacy they left behind them towards the building up of a native medical tradition in Wales, but it is legitimate to surmise that at least some elements of the lore of Hippocrates and the great Greek medical tradition may have made their way into Britain with the legions, and, once implanted there, may have lingered, as the *longue* of the legionaries lingered after their departure, in Cornwall, in Cumberland, and in Wales. It is a significant fact that the modern Welsh word for a physician, the word *meddyg*, goes back directly to Roman times, being derived from the Latin *medicus*, and occurring first in its Welsh form in the old Cornish vocabularies.

After Rome, the welter of the Dark Ages—a period dark to the historian everywhere in Europe, but darkened still more in Wales owing to the distrust to which many of the manuscripts relating to the period are subject. Not until the beginning of the tenth century, and the codification of Welsh Tribal Law about that time, do we come upon reliable information regarding the profession of medicine.

A thousand years ago King Hywel the Good caused the Laws of Wales to be codified, and it is in these codes that we get the first authentic glimpses of our profession and the manner of men who practised it in tenth century Wales.

This monarch had a court physician who was given place and prestige in his presence, had a grant of free land and a horse, and received his linen clothing from the Queen and his woollen clothing from the King. His seat in the hall within the palace was at the base of a pillar near to the King and his lodging was with the chief of the household. It was his duty to administer medicine without charge to all within the palace, and to the chief of the household. It would appear that he was a whole-time officer, with intervals when, on the basis of a moderate tariff, he was allowed to enjoy the stimulating freedom of private practice. He had to accompany the armies, but ordinarily he was never to leave the palace without the King's permission, when he was free to take any road or route with the messenger of the sick. In those days it was lawful for anyone to take another's horse to procure a medical man for a person in danger, without being required to make amends. The same principle applied to-day in respect to motor cars might lead to serious misunderstandings.

The chief interest of these early codes, from a medical point of view, lies in the way they assessed legal damages for injuries and laid down standard fees for treatment. The thumbnail, for instance, was worth thirty pence. One front tooth was equal to a finger, one molar tooth to a thumb.

MEDIAEVAL TRANSITIONS

The old laws are interesting as showing us something of the state of the Welsh *meddyg* under the Welsh tribal system in the tenth century. The eleventh century brought with it great changes in Welsh history. A great new formative influence came then into the life of Wales—that was the Norman. The Norman affected profoundly the whole course of Welsh life and politics. Under the walls of his castles there grew up townships, markets, fairs. Once more, as in the days of the early wandering Celtic missionaries, Wales came into touch with the rest of Europe and the world. For not in Wales and England only, but in Ireland, in France, in Spain, in Sicily—in Palestine even, on the threshold of the immemorial East—there too were the castles of the Norman. Pilgrim and Crusador, merchant, monk and friar, errant knight and troubadour, all whose activities helped to render knowledge fluid and international throughout the Holy Roman Empire, must have helped towards the building up of a native medical tradition in mediaeval Wales, a tradition which has left behind as its monument a fourteenth century manuscript, the older of the two manuscripts known as the "Books of the Physicians of the Myddfai."

It was but natural that the tradition of the physicians of the Myddfai in mediaeval Wales should trace its origin back to the fountain head of a legend.

In the fastnesses of the wild Fan Mountains of Carmarthenshire there is hidden away a small lake known as Llyn-y-Fan Fach. Long ago, so the legend runs, a shepherd boy named Gwyn was tending his flock on the shore of the lake when a most beautiful maiden emerged from the mirrored surface of the water. After many complications, which are so essential to a fairy tale, Gwyn and the maiden of the lake became man and wife. Three sons were born to them, but after a time the maiden disappeared again into the depths of the lake, taking with her her fairy dowry of cattle and chattels. At a later day, however, she reappeared to her three sons, who kept vigil for her on the shore. The eldest son, Rhwallon, she led aside to Pant-y-Meddygon (the Physicians' Hollow), there she revealed to him the properties of the medicinal plants and herbs which grew around them, and called upon him to dedicate himself to the art of healing. Thus Rhwallon did, so that he became the physician to Rhys Grug, Lord of Llandovery and Dynevor. Tradition claims, too, that the descendants of Rhwallon practised their art at Myddfai in unbroken lineage until the end of the eighteenth century.

Such, in brief, is the story of the physicians of Myddfai. Interesting though these earlier figures may be, however, it is only after the Renaissance had rejuvenated Wales that we come upon the beginnings of a really broad-culture among Welsh physicians. Although not one of the outstanding physicians of Wales in Tudor and early Jacobean

times had any claim to be compared to a Sidenham or a Harvey, they were yet figures commanding interest and respect in other ways. Educated, most of them that we know of, at the older English universities, their medical writings and their medical beliefs were, for their day and generation, reasonable and scientific. One striking characteristic which many of them had in common was the great breadth of their culture and their scholarly achievements in other arts besides medicine. Thus Phaeor of Pilgerau was one of the first great Elizabethan translators of the classics, while to Robert Recorde of Tonby we owe the introduction of the study of algebra into this country.

Time does not permit to follow the fortunes of the Welsh *meddyg* through the seventeenth and eighteenth centuries. Something of their ubiquity and prominence may be gathered from the fact that the two surgeons on board Captain Cook's ship the *Resolution* in 1777 were Welshmen—Robert Davies of Wyddgrug and David Samuel of Denbigh. Samuel later became surgeon of the *Discovery*, and he may have suggested to his captain some of the latter's very enlightened ideas regarding the relationship of scurvy to diet. At any rate, Samuel was a scientifically minded man, as shown by his treatise on the introduction of certain diseases among the South Sea Islanders. "He was," so wrote one of his contemporaries, "extremely irritable, but one of those hearty fellows we expect a sailor to have been."

But however true it may be that the past, even the distant past, is ever with us and must tincture our every thought and deed, the blend of the present and the immediate future is the main incentive to individual and corporate action.

HEALTH ORGANIZATION IN RECENT TIMES

The population of the world to-day is many times greater than it was a thousand years ago, and over the average of years Mother Earth shows no signs of failing to respond to the food and other requirements of her increased family of humans. Correspondingly, however, much more work has to be done by these humans in order to extract and prepare these requirements. Effective work involves a sufficient measure of health, and hence, perhaps, one factor at least of the instinctively higher regard for the health of the individual and of the community which is so marked a social feature of the day.

The demand is insistent, and from the nature of the case the supply can never wholly meet it. But quite wonderful achievements have been registered by organization and scientific discovery. At the same time those who know most know how much more remains to be done.

A sign of the times, that enactment of outstanding importance the National Health Insurance Act, 1911, which provides domiciliary medical attendance for, say, sixteen million of the forty-five million of the population, has profoundly modified and to a significant extent refocused the conditions of the great bulk of medical practice in this country.

Piloted with great ability and energy through a half-reluctant House of Commons by Mr. Lloyd George, the then Chancellor of the Exchequer, and menaced by vested and otherwise disturbed interests, this colossal measure came into operation in the early days of January 1913. The unavoidably complex machinery of so far reaching an Act was but as yet in the stage of graduating through the inevitable jolts and jars when the cataclysm of the great war and the disabilities of demobilization intervened as a further strain on administration.

It says much for the administrative staff and even more for the 15,000 medical practitioners accepting service under the Act that as set forth in the Memorandum of Evidence submitted by the British Medical Association to the Royal Commission on National Health Insurance both the Representative Body of the Association and the Conference of Representatives of Local Medical and Panel Committees agreed "that the measure of success which had attended the experiment of providing medical benefit under the National Health Insurance Acts system has been sufficient to justify the profession in uniting to ensure the continuance and improvement of an insurance system."

It is demonstrable that insured persons under the Act,

taken as a whole, are provided with a better grade of medical service than were their equivalents before its inception. But of the making of regulations there is no end, and the officials concerned, and certainly the busy practitioner, may well be forgiven if, on occasion, a lapse of memory leads to executive error. It would be a real boon to the insurance practitioners, to the officials, and to the insured persons, and would prevent many mistakes and misunderstandings, if someone—it would admittedly require little short of a genius—would intelligibly collate the multitude of regulations.

Under the Act as it stands much more could have been done and should be done, in the matter of wise propaganda directed to the means of preserving health and of preventing disease but, taking the Act in general, with its many inherent administrative difficulties, it can be said that the major provisions are being sympathetically and effectively implemented. But the degree of success so far attained in itself calls for further and fuller developments, which in due course should be equally available for all insured persons regardless of their membership of any particular society.

Such further provisions should include complete consultant and specialist advice and treatment, and, under conditions, nursing and massage. Various salient advances by some of the approved societies have already been made into the region of these developments, notably in the form of dental, ophthalmic, or institutional extra benefits, and the experience and results accruing will, doubtless, ultimately encourage an advancement of the line, as indicated in recent enactments by Parliament.

In such logical and, indeed, inevitable developments of the health insurance scheme, stage by stage being added after full consideration of the reasonable interests of those concerned, I for one fail to see the risk of any sudden ultimate transmutation to a whole-time State medical service, with its connoted and handicapping officialism and sacrifice of personal freedom.

PROGRESS AND RESEARCH

To endeavour to compass, even in outline, anything of the nature of an informing survey of the advances of medicine and surgery since the Association last assembled in Cardiff, or even in the past twenty years, would obviously be impossible on such an occasion as the present. The achievements are stupendous, and represent a vast saving of human suffering and an appreciable prolongation of human life.

These results are not the product of knowledge acquired casually or in haphazard fashion. It is true that enlightenment may come, at times, from unexpected quarters, but the basis of real advance has been framed, as it always will be, in the tireless, persistent, relentless toil of our research workers, whose faithful services are so often unrecognized and unequited.

Happily for research in general, it would appear that successive Governments in most civilized countries are becoming increasingly aware of their obligations in regard to the provision of adequate funds for the acquiring of new knowledge, as well as for the costly machinery of imparting knowledge already gained. The latter avenue of disbursement is a real necessity, but, under conditions, the claims for moneys to support pioneer work in the as yet unknown but assuredly rich fields calling for it must be accorded a high status.

It may be usefully added that those who provide the means and facilities for research work must be as patient as the workers themselves. To call early for results, and thus, possibly, to bring about the premature announcement of findings, is to render a lasting disservice to research and to many unfortunate people who may be even vitally concerned. In most inquiries the problems are manifold, and the route to the objective is never by an "A" road in a fast car, but is almost always o'er moor and fen, errand and torment, involving many readjustments and delays. An element of fascination is that it is often in the byways—that is, in the collateral issues raised in the conduct of a piece of research—that treasure of the greatest value is found.

The occasion is not suitable to review in detail the advances in medicine in the past few decades. But on the crest of the wave of recent years ride prominently the bacteriological and biochemical discoveries, the latter even overshadowing the former, as witness the new science of the endocrines, the chemistry of body fluids, the functions of organs as expressed in their influence on the composition of the blood—for example, liver and spleen—and, lastly, the vitamins. Incidentally, such a recital provokes the reflection that if one of the old alchemists came to life in our midst to day, after the manner of Rip van Winkle, in all else but technique and terminology he might find himself very much at home.

As regards endocrinology, we will not, of course, agree with one enthusiast who claims that the blood, the nervous system, and the glands of internal secretion form a triumvirate of chemical machines whose interpreted functionings constitute the soul, nor when he proclaims that there is every reason for believing that life is a piece of chemical clockwork. Nevertheless the supreme importance of these glands has been proved beyond all question, and the therapeutic results of organotherapy are becoming day by day more clearly and scientifically appreciable. The thyroid, the parathyroids, the pituitary, the adrenals, are almost household words, and who has not heard of that wonderful product of modern alchemy with which the name of Banting of Toronto is so prominently associated—insulin?—a drug which has given life and the promise of life to many thousands at the hands of the physician, and one of whose especial values it is that by its preliminary and coincident use an avenue has been found opening towards curative surgery for many conditions hitherto denied that advantage.

The topic of vitamins, descended upon in the pulpit and press, from within the profession and by para-professionals, would appear to have entered into the web and woof of the national life, and no home is complete without it. You can have them arranged alphabetically or numerically, and, if preferred, in concentrated form. It may interest the younger and less robust members of the community to know that the vitamin content of a ton of cod-liver oil can be reduced to about one quart.

A striking feature is the large and over-growing number of instances in which the bacterial origin of disease has been and is being constantly discovered, and in which accordingly treatment is being more effectively directed. Many other diseases, further, in which the course and symptom-complex give good grounds for the assumption that they are of simular origin, are receiving close attention, but so far the miscreant germ is perhaps even more difficult to identify than the ill-doer in an obscure case in a process of law.

With regard to tuberculosis there is little to add to what was said in the classical address of my predecessor, Sir Robert Philip at the Edinburgh Meeting last year, except that already there are signs that some of the forecasts in that exceptionally able pronouncement are being materialized.

Of late years thought and deed have turned dramatically towards the prevention of disease, and, shadow-like, immunology dogs the footsteps of bacteriology.

Among the general diseases pernicious anaemia, by the liver treatment first applied by G. R. Minot and W. P. Murphy of Boston, has been brought within the pale of substantial amelioration or even cure.

The Association has taken an active part in the investigation on a wide, thorough scale of that most prevalent and disabling condition—rheumatism—and the statements and recommendations of the latest report should do much to establish a machinery calculated to control, at all events, the main features of the problem.

The cause, whether it be single or collective, of that dread disease, cancer, still eludes, will-o'-the-wisp like, the grasp of the intensive research which has been and is being conducted in the clinics and laboratories of the world. The ears of multitudes are indeed attuned to listen in to any glad news of a discovery, but the public and the press may be well assured that whencesoever the claim may arise it will be, in the interests of the whole community, submitted to sympathetic but close examination.

by those who are best qualified to judge. Nothing can be more deplorable in its results than the premature announcement of claims as to causation or successful treatment of so prevalent a malady.

Meanwhile, the wisely directed propaganda which has been carried on has undoubtedly had a widespread effect in inducing many people to seek advice when the earliest possible manifestations of the disease have appeared, and so becoming included within the ambit of definitely curative treatment. Indeed, apart from the presence of symptoms, in an increasing measure people are now coming to observe the wise precaution, more prevalent in America than in this country, of being overhauled or "checked-up" at intervals by their medical attendants. By such a practice the pre-symptomatic stage of disease may be detected and effectively dealt with.

Passing reference only is permissible to the veritable pageant of advancement in the science and art of surgery—a pageant largely made possible by the brilliant work of Pasteur and of our own Lister, whose imperishable memory was so universally appraised in his centenary year.

MATERNAL MORTALITY

It has been urged, and with truth, that one of the most vitally important branches of medical practice—obstetrics—has not shared in due proportion the benefits accruing from the Listerian epoch with regard to the incidence of infection. Many persons, and many interested bodies, including the Ministry of Health and our Association, have been, in their several spheres, devoting time and earnest attention to the problem, and it is of the first importance that Her Majesty the Queen has personally associated herself with the movement to investigate adequately the governing causes and to endeavour to reduce the maternal mortality and morbidity rates.

No further incentive to this end need be furnished than the oft-quoted facts that more than 3,000 mothers lose their lives every year in England and Wales—that in more than half of this number death is due to septic infection, which, it is claimed, is, or should be, a preventable condition. Preventable, yes, given certain conditions. It is well known that under properly conducted institutional conditions mortal septic infection arising *de novo* is reducible to vanishing point. In these establishments the observance of every detail and circumstance of technique designed to secure asepsis can be carried out, and a confidence generated akin to that with which surgery in general is now undertaken.

Inasmuch as, in a country like ours, all cases, or any very considerable proportion of them, cannot be institutionally provided for—the total in England and Wales would require something like 30,000 beds—the problem would appear to be capable of solution if it were possible to reproduce in the homes of the people the essential factors of this provedly effective hospital treatment. This deduction loses little of its force even if it be urged, as with truth it may, that on the one hand there are some rapidly fatal cases of infection in which every known precaution has been taken, and, on the other hand, that some difficult and complicated cases, in the circumstances of which practically no precautions can be observed, may make a smooth recovery. Such cases are the exception and not the rule.

To reproduce, however, in the average home that veritable Temple of Asepsis, the operating theatre, with its ministering priests and priestesses, is, of course, impossible. But to be effective the ritual need not be complicated, and the association of ante-natal care and, if necessary, treatment, the adequate nursing, the unharmed waiting upon events in suitable cases, and the availability of skilled experience of all kinds if and when required, are equally indispensable elements in the right kind of institutional treatment. There are thousands of general practitioners who, in letter and in spirit and wherever possible transmute the largest common denominator of these hospital advantages into their practices, and their results attest the fact.

Every practitioner, however, and especially in certain districts, must not rarely encounter such conditions of

poverty, ill-housing, previous unskilled interference, and other handicapping circumstances, as render it impossible to practise asepsis, and where accordingly the pathways to infection are hopelessly unguarded. It is gratifying to note that several local authorities are doing much to meet the circumstances of many who cannot afford even a very inexpensive equipment—the maternity benefit notwithstanding—and that the sequel is encouraging.

It is much to be hoped that at no distant date the recommendations submitted by the Association to the Royal Commission on the Insurance Act in regard to this supremely important branch of medical practice will be materialized.

Meanwhile the tendency exhibited in certain quarters to make the general practitioner the scapegoat for the sins of many is to be deprecated. To begin with, he cannot be sent into the wilderness. In his hands, either in original charge or as a consultant of first instance, must lie the application of the standard obstetrical practice of the day for the great bulk of domestic cases. He needs not blame, but support in the form of the provision of facilities in suitable cases to cope with this most anxious, time-absorbing, underpaid factor of his work. As it is his devoted response to its calls in most difficult circumstances is worthy of all praise.

There are many aspects of this international problem which are baffling, and one cannot but earnestly hope that the intensified research which is now being directed not only into its bacteriology but also into the question as to the factors which constitute and the conditions which vary resistance to infection, may produce helpful light and leading.

INTERNATIONAL CO-OPERATION

This and many other important topics of international concern are engaging the close attention of the appropriate departments of our Annual Meeting. Indeed, we are, by the presence with us on this occasion of so many distinguished representatives of other countries and other climes—whom we are delighted to have the privilege of greeting—strikingly reminded of the cosmopolitan character of the science and art of Medicine. Orthodox medicine knows no protection barriers and claims no patent rights. The international pooling of ideas, of discoveries, and of experiences is essential to the recognition of even a datum line of the advances in the various departments.

There is an impression abroad—and it is not, perhaps, ill founded—that in the British Isles we do not sufficiently organize and utilize the wealth of clinical material at our disposal for post graduate demonstration in the interests of our home profession and of visitors from other countries. Good work has been and is being done in the various metropolitan centres, but these do not claim a monopoly of skill and clinical facilities. I have long felt that with its wonderfully ramified machinery to link up the provinces and the capital, the rural areas and the towns, no body is so well adapted as our Association to organize a post-graduate system embracing existing institutions and developing many new centres, on a scale worthy of this country.

I am not without hope that there may be forthcoming a national, nay, an international, benefactor willing to entrust the Association, as a voluntary body with the considerable sum of money necessary to establish and conduct such a system. I am convinced that thus we would not only raise the standard of efficiency, and therefore of health in this land but colleagues from overseas and other lands would find it more than ever worth their while to spend some time with us, to our mutual benefit. The advantages would not be limited to our professional spheres, but would surely develop in wider measure social and ethical results of far-reaching significance.

No branch of the League of Nations exerts a wider general influence than the Health Organization, the head of which, Dr Rajchman, we are so glad to have with us. That influence is not accidental. It is essential. For may we not in all humility venture to claim that no other profession or calling can offer a basis of union so broadly appealing to what is common to mankind as the objective of preventing, alleviating and curing the diseases of humanity?

THE MODERN TREATMENT OF HERNIA BY TRUSSES *

BY

W. McADAM ECCLES, M.S., F.R.C.S.,
CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

THE operative treatment of hernia has become so widespread during this century that the mechanical retention of viscera within the abdomen is likely to become a lost art.

Undoubtedly hernia is amenable to successful treatment by operation in its early stages in suitable subjects, and the perfection to which such operations have been brought brings credit upon surgeons of many lands. But there will be for many years yet to come, and perhaps for the rest of time, quite a number of herniae, all of which are important because they constitute a danger to the sufferers, in which a truss may be the sole method of treatment. It has been my good fortune to gain experience of this type of instrument over a considerable number of years, and I make no apology for bringing before you in this British Medical Association Lecture some simple but practical points relating thereto.

It can be imagined with what consternation the first case of strangulated hernia was regarded by our ancestors. When it became recognized that the terrible condition, ending usually in death, was due to the gut passing into a pouch, all sorts of attempts began to be made to retain the intestine within the abdomen. There is in the Wellcome Historical Museum an Egyptian statuette wearing a truss, and it reminds me of some of the crude apparatus sold at exorbitant prices in the twentieth century, and I suspect it was as efficacious.

The variety of forms of trusses, even for one type of hernia, tends to prove that retention of prolapsed organs is not so easy a matter as some would think. The torture, literal torture, that some patients have suffered, and some still do suffer, from the improper instruments applied to their bodies is indicative of a want of knowledge of proper truss treatment.

ESSENTIALS OF A GOOD TRUSS

What, then, are the essentials of a good truss? They are (1) close fitting, (2) ability to act when occasion for its function arises, (3) comfort, (4) durability, (5) economy in cost.

Close Fitting

It is obvious that a truss which does not fit closely to the body is likely to become shifted in the movements of the wearer and so to become worse than useless—to become, in fact, a false security. It is for this reason that a truss should be worn next the skin, and not with intervening clothing.

But a truss may fit so closely as to become a constricting culet, and this is particularly so in those types in which there is an elastic band passing round the pelvis. I have seen instances where the band, having been worn low down and tightly across the buttocks, has caused actual interference with the functions of the sciatic nerve.

Close, but comfortable fitting, implies careful measurement for, and making and adjustment of, the apparatus. It requires some practice to measure even for a simple inguinal truss, it further requires considerable skill in the proper manufacture of the truss to the measure, and still more a good knowledge of anatomy for its right adjustment.

Let us take the question of measurement first, and for an inguinal hernia. The tape must not pass horizontally round the pelvis—a mistake very frequently made—but obliquely, because when applied the truss has to lie obliquely. Therefore the tape must be placed high up behind, at the base of the sacrum, just below the anterior superior spines at the sides, and at the level of the upper part of the symphysis pubis in front. It is extraordinary how few know where this latter point really is, so many placing it much lower down than it actually exists. No attention should be paid to any "ring," partly because it is only confusing to do so, and partly because such

things do not exist. The exit from the inguinal canal is still often called the "external abdominal ring," which is altogether a misnomer, for it is not "external" but "superficial," it is not "abdominal" but "inguinal," and it is not a "ring," which is a circle, but it is a "triangle." So that a much more suitable, in fact the only correct, term for this exit is the "superficial inguinal aperture." It may also in passing be pointed out that this aperture has nothing whatever to do with the incidence of inguinal hernia, and the passing of the tip of the finger of an examining medical practitioner is indefensible. When measuring for a single truss the actual measurement taken is the right one to forward to the truss maker.

If the patient requires a double truss, it will be well to add an inch to the actual measurement, as a double truss does not give at all.

Ability to Act when Occasion for its Function Arises

No proper truss should exercise pressure which is irksome to the wearer, but it should be able to bring pressure to bear over the hernial aperture when any marked increased intra-abdominal pressure arises, such as that occurring in coughing, sneezing, and defaecating. In connexion with this property of a truss, it should be emphasized that of all types of truss the one with a metal spring passing at least three-quarters of the way round the pelvis has proved to be the most comfortable and efficient.

The curve of the spring is important, for if this is too marked it will make the pad exercise injurious pressure. The curve should be such as to cause the spring to give the pressure needed when an expulsive effort is trying to force the viscera into the sac. The tempering of the steel must be perfect if the best is to be obtained from the truss. It must be so good as to allow of the spring being opened out completely without snapping. In a single truss the end of the spring must be hammered thin—bevelled—so that it will give and adjust itself to the patient's body, and have no tendency to force its way through the leather covering at its termination. This is one of the best tests between a well-made and a poorly made instrument.

Comfort

No truss which is uncomfortable can be considered satisfactory. It will certainly not be by the wearer, and it should not be by the prescriber. But comfort with efficiency is not always easy to secure. There is the personal equation of the patient, the skill of the manufacturer, and the materials from which the truss is made. An ideal truss is one which, while holding the viscera within the abdomen, causes the patient less discomfort than does either of his boots. Or, to put it in another way, one which is merely part of his clothing.

In a truss with a metal spring and pad there are two chief causes of complaint. One is the friction and the pressure of the spring over the parts behind on the back, and at the sides below the anterior superior iliac spines. In thin subjects it is sometimes difficult to secure complete comfort at first, but it is wonderful how soon, with patience and perseverance, discomfort disappears.

The other cause of trouble is the actual pressure of the pad or pads at the site of the hernial aperture or apertures. Much of this is due to faulty construction of the pad or a wrong direction of the curve of the spring. Both can be overcome by a little knowledge of the proper manufacture of a truss. For a long while now I have been using a honeycomb rubber facing to the pad beneath the chamois leather covering. This is a sponge, consisting of a multitude of air cells, and it not only exercises a soft pressure but tends to mould itself to the body. The idea has not been patented, and is to be commended. The improper curve of the spring simply should not occur if the truss has been properly constructed. Further, comfort can be ensured by care of the skin, which has not as yet become accustomed to the unusual pressure upon it.

Close attention must be given by the wearer to keep the skin clean and dry. Ointments, vaseline, or cold cream must be rigidly forbidden, but a little friction with methylated spirit or eau de Cologne, night and morning, for the first few weeks tends to harden the skin and keep it fairly aseptic. In addition, a light powdering each morning, after the application of the spirit, with a powder

consisting of one part of boric acid, one part of zinc oxide, and two parts of fine starch powder, is helpful to keep the skin dry where the pads press.

Tact, persuasion, and sometimes a little threatening, all have to be used in dealing with patients, particularly with those who, having been careless, have allowed their hernias to get out of control. It is wonderful how a comfortable and efficient truss conscientiously worn will diminish the size of the protrusion of the hernia, so much so that sometimes a patient will consider himself cured and unwisely discontinue with the truss, and then find that the hernia recurs.

Not very infrequently the application of a truss to an easily reducible but large hernia will render a subsequent operation more simple and more sure of satisfactory results.

Durability

All the materials from which a truss is made must be good, and one made from cheap materials will wear out in a short time. Hence a good truss made by hand from the best materials cannot be a cheap article, but one for which a good price must be paid.

Well tempered steel, made as far as possible rustless, reliable leather covering and neat sewing all tend for long life of the appliance and satisfaction to the wearer. It is distressing to see the shoddy specimens sometimes sold even by respectable firms, and all practitioners should know a good truss from a bad one.

Economy in Cost

From what has been said the real economy in cost is to have, in the first instance, a well made, well fitting, and durable truss. Then to secure a second one made of the same type as soon as it is proved that the original is satisfactory, and to counsel the patient to wear them alternately week by week. In this way each will last longer, and, should one happen to go wrong, there is the other already comfortable and ready to wear whilst repair or renewal is being carried out.

In the treatment of hernias by trusses close co-operation is required among all the three parties concerned—the patient, the practitioner, and the manufacturer. Personally I am certain that the patient should not go to the manufacturer, but the practitioner should measure for and adjust the instrument himself to his patient. This implies naturally a sound knowledge of the type of truss required, of the method of measurement, of the proper manufacture, and of anatomy for adjustment. It is for this reason that it is most desirable that all students should continue to be taught well the essentials concerning the modern treatment of hernias by trusses.

[The lecture was followed by a demonstration of trusses and their application to a living man.]

THE MECHANISM OF BLACKWATER FEVER AND CERTAIN ALLIED CONDITIONS

BY

D B BLACKLOCK, M D, D P H, D T M,
PROFESSOR OF TROPICAL DISEASES OF AFRICA THE UNIVERSITY OF
LIVERPOOL

AND

G MACDONALD, M B, Ch B, D T M,
RESEARCH ASSISTANT, SIR ALFRED LEWIS JONES LABORATORY,
FREETOWN, SIERRA LEONE.

BLACKWATER FEVER is without doubt the most important and serious disease affecting Europeans in tropical countries, not even yellow fever can compare with it as regards mortality. It is difficult to overestimate the retarding influence of this infection on the development of our tropical possessions. Apart from the regrettable loss of men who are just beginning to render valuable services to their country, there is the depressing effect on the surviving European population in endemic areas. The fever is regarded with great dread by the latter, and is a cause of grave anxiety to medical practitioners where it exists.

The etiological theory which we now present is believed to be entirely new, but the evidence which we have obtained would seem to warrant our belief that it is correct.

DISTINCTIVE BIOLOGICAL FEATURES OF *P. FALCIPARUM*

It is to-day generally agreed that blackwater fever arises mainly in the course of prolonged infection with *Plasmodium falciparum*. As there is no evidence that the malignant tertian parasite produces a toxin which differs from that of the other malaria parasites, we must seek for the explanation of this association between blackwater fever and *P. falciparum* in some biological factor other than toxin production.

The outstanding differences between *P. falciparum* and the other malaria parasites are that the former sporulates not in the peripheral blood but in the internal organs, and that the cells containing the sporulating forms adhere to each other and to the vessel walls. These phenomena were observed in the early work on the malaria parasites, and have been constantly recognized. Marchafava and Bignami,¹ in 1894, said of malignant tertian malaria, "Malignancy coincides with an exceptionally abundant quantity of parasitic forms, a quantity much more abundant—where the cases terminate fatally—in the blood of the viscera than in the blood of the finger." Christophers and Bentley² noted that it was in infections by the malignant parasite that the organs were found to be most actively engaged in holding up the infective red cells, the very perniciousness of infections by this parasite being suggestively associated with such an action. Three observations serve to explain this tendency of the malignant tertian parasite to accumulate in the internal organs. Marchafava and Bignami¹ drew attention to the fact that corpuscles infected with malignant parasites, especially of the adult form, have lost their elasticity, and consequently resist the change of shape necessary for their passage through the capillaries, an observation which was again made by Bass.³ Next Thomson and Thomson² recorded and illustrated marked clumping of the infected red cells in culture during all stages of sporulation of *P. falciparum*, whereas no tendency to clumping occurred in cultures of *P. vivax*. The two observations so far mentioned would account for the accumulation of the sporulating forms of *P. falciparum* in the capillaries of any part of the body, but not necessarily in the internal organs. Their predilection for the internal organs was explained by Bass, who showed that they lodge in those capillaries where the current is weakest or where slight obstruction is produced by the protrusion of endothelial cells inward. The commonest and most important site of this massing of infected cells is the spleen, though the bone marrow and other organs may be similarly affected. We may allude here to the massive infections found by Clarke⁴ in the placentas of parturient women, even in cases where the peripheral blood was free from parasites, a finding which was confirmed by Blacklock and Gordon.⁵

We are convinced that the association between blackwater fever and *P. falciparum* must depend on these distinctive biological characters of this parasite, we hope also to make it clear that as a result of these very characters of the parasite the condition known clinically as blackwater fever has fundamental affinities with several other forms of haemoglobinuria and haemoglobinemia.

DEFICIENT OXYGENATION IN THE HAEMOGLOBINURIAS AND HAEMOGLOBINAEMIAS

We have selected for comparison with blackwater fever a group of haemoglobinurias and haemoglobinemias which seem at first sight to have little relationship to each other, but which on closer investigation reveal notable features in common. The group includes haemoglobinuria in pernicious anaemia complicated by venous thrombosis, haemoglobinuria in Raynaud's disease, haemoglobinemia in dogs as a result of exercise, haemoglobinuria in man from marching and myoglobinuria in horses. One feature common to all these conditions is the existence in them of a state which results in deficient oxygenation, either local or general, the manner in which this state is brought about may be considered under the various diseases.

1 *Blackwater Fever*—In an earlier paragraph we have described how the sporulating malignant tertian parasites adhere to each other and to the vessel walls, forming large agglutinated masses in the internal organs. Deficient oxygenation naturally follows, and the pre-existing malarial anaemia accentuates this local oxygen deficiency.

2 *Pernicious Anaemia Complicated by Venous Thrombosis*—Panton and others⁴ describe two cases of repeated haemoglobinuria in men who had a clinical condition and blood picture suggestive of pernicious anaemia, complicated by the presence of thrombosis of superficial veins. The existence of an oxygen want is inevitable in this combination of general anaemia and local stasis of blood, a condition which has a definite affinity with the conditions present in cases of blackwater fever.

3 *Raynaud's Disease*—Haemoglobinuria is the most remarkable complication of this condition, and occurs in a considerable number of cases. As a rule the urinary changes are only met with during the existence of local cyanosis, and the attacks are more likely to come on when the patient is up and about, when the patient is put to bed the haemoglobinuria may cease. Haemoglobinuria has also been observed. In Raynaud's disease there is local deficiency of oxygen, brought about by spasm of the arterioles.

4 *Haemoglobinuria in Dogs after Exercise*—Hasting,⁵ has described the frequent occurrence of haemoglobinuria in untrained dogs which are subjected to running exercise.

5 *Haemoglobinuria from Marching*—Stephens¹⁰ has collected the records of twenty-three cases of haemoglobinuria due to marching in otherwise normal persons. It seems legitimate to infer that this form of haemoglobinuria frequently occurs without being noted, because I myself, in examining twenty-six persons after a long march, found haemoglobinuria in no fewer than eighteen, or about 70 per cent of them.

6 *Myoglobinuria in Horses*—Stephens also refers to the myoglobinuria which occurs in horses, long stabled on rich food, when they undergo sudden exposure to cold or exertion, either factor being said to suffice. As regards the untrained dogs mentioned above, there is clearly established in them an oxygen debt. It is similarly evident from the description of the cases of haemoglobinuria due to marching that, with one possible exception, sufficient exercise was taken to result in an oxygen debt, the exceptional case was that of a boy who also had marked postural albuminuria.

We have drawn attention to the fact that the members of the group have the state of anaemia in common, a difference between them lies in the manner in which this state is brought about. Whereas in blackwater fever the malignant tertian parasite plays an obviously important part, in the other diseases very different agencies are at work producing the same result.

If we next consider the effects which arise from deficient oxygenation in the animal body, we shall observe how these effects influence the production of haemolysis in the selected group, taking blackwater as our type.

DEFICIENT OXYGENATION AND LACTIC ACID FORMATION

The Effects of Deficient Oxygenation—Recent work by Hill, Long, Lupton, Fuiusawa, and others¹¹⁻¹⁴ has resulted in a considerable advance of knowledge of carbohydrate metabolism. Carbohydrate in the form of dextrose is brought by the blood stream and stored in the muscles as glycogen; the glycogen is converted into "lactacidogen," a hexose diphosphate, which is a compound of a monosaccharide and phosphoric acid. This is a readily dissociable compound which, on muscular contraction, is broken down into phosphoric acid and sarcolactic acid, the reaction is anaerobic. When the oxygen supply is sufficient one-quarter to one-sixth of the sarcolactic acid is oxidized and some of the chemical energy thus liberated is used to resynthesize the rest of the sarcolactic acid to lactacidogen. In excessive exercise the body is incapable of immediately supplying sufficient oxygen, and the lactic acid accumulates to a maximum of 0.45 per cent in the muscles and 0.2 per cent in the peripheral blood. The lactic acid produced is neutralized only slightly by the

carboate of the plasma, the main reaction being with the sodium proteins, forming sodium lactate and an acid protein, the chief protein used for this purpose when lactic acid is liberated in the blood stream is haemoglobin. There is thus a definite acidosis in exercise, due to the presence of unionized protein. The metabolism of carbohydrate in the other tissues of the body also produces lactic acid as an intermediate stage, though possibly not by an identical mechanism.

It is very important to note that this cycle of carbohydrate transformation is a continuous one even in the normal resting state, when there is no visible evidence of muscular activity, it follows, therefore, that if for any reason there is a deficient supply of oxygen, lactic acid will accumulate. This has been demonstrated by Clausen,¹⁵ who noted a marked increase in the lactic acid content of the blood of adults with cardiac decomposition and infants with anhydramia from diarrhoea, both being conditions causing anaemia by circulatory disturbance. Macleod¹⁶ produced a great excess of lactic acid in the blood of dogs by making them breathe an atmosphere deficient in oxygen.

The normal quantity of lactic acid in the blood of the resting individual is approximately 20 mg per 100 c.c., the following table shows the effects produced by exercise and deficient oxygenation.

TABLE I.—Showing the Quantity of Lactic Acid in the Blood after Exercise and Anaemia

Author	Subject of Experiment	Condition	Lactic Acid mg. per 100 c.c.
Hill Long Lupton (1924)	Normal individuals	Severe exercise	80-100
Hill Long Lupton (1924)	Trained athlete	Severe exercise	204
Clausen (1925)	Adult (human)	Cardiac decomposition, Anhydramia	160
Clausen (1925)	Children	Anhydramia	25-150
Macleod (1921)	Dogs	Atmosphere containing only 5% of oxygen	98
Macleod (1921)	Dogs	Extreme anoxia	123

The table illustrates how deficiency of oxygen from whatever cause always produces an excess of lactic acid in the blood. In view of the fact that all the haemoglobinurias and haemoglobininaemias which we have included in our group are associated with oxygen deficiency, we are driven to the conclusion that in each of them excess of lactic acid is produced.

That some normal product of body metabolism such as lactic acid is involved in the haemolytic process of blackwater fever appears probable from the facts which have been mentioned above. The etiological resemblance between blackwater fever and the other conditions in respect to anaemia has been shown. Now in certain of these latter conditions it is assured that the cause of the haemolysis is some natural product of the animal body, this is best seen in the experiments resulting in haemoglobinuria in normal dogs and in the observations on haemoglobinuria in man caused by marching, where haemoglobinuria is induced simply by exercise. It appears, therefore, essential to investigate what haemolytic properties lactic acid possesses.

HAEMOLYTIC PROPERTIES OF LACTIC ACID

In our first experiments we used a sample of commercial lactic acid which was in stock in the laboratory, this acid proved haemolytic up to 1 in 1,000, using a 10 per cent cell suspension of normal human blood which had been defibrinated, the sodium and ammonium salts prepared from the acid proved non-haemolytic. We did not perform any animal experiments with these substances as the racemic form does not occur in the animal body. In our next series of experiments with lactic acid we used a sarcolactic acid which we ourselves prepared according to a textbook technique, this substance was discarded after several months' experimentation *in vitro* and *in vivo*, as it was then found that the presence of impurities in the acid

made the results of our experiments unreliable. We therefore obtained from Dr Martindale a supply, as pure as possible, of sodium and ammonium dextro-lactate and also of dextro-lactic acid itself. The sodium and ammonium salts proved non-haemolytic, in any concentration possible in the human body, to human red cells *in vitro*. The acid proved highly haemolytic to suspensions of thrice-washed red human cells in saline solution—for example, complete haemolysis was obtained in a dilution of 1 in 600 and slight haemolysis in a dilution of 1 in 1,200, when a 10 per cent suspension of cells was used. The use of suspensions of washed cells, although of value in demonstrating the presence of a haemolytic agent, is somewhat artificial in that it does not allow for the protective action of the plasma. We therefore tested the acid on blood approximating as nearly as possible to its normal condition, as in the following experiment.

Five cubic centimetres of blood were withdrawn from the vein of a healthy European into 0.5 c.c. of 1 per cent solution of sodium citrate in normal saline. A series of tubes was then put up each containing 0.8 c.c. of this blood and 0.2 c.c. of a dilution of the acid. Table II shows the result of the experiment after three hours incubation at 37°C.

TABLE II—Showing the Haemolytic Effect of Sarcocactic Acid on Human Blood

0.2 c.c. of Lactic acid Strength	Citrated human blood	Final dilution of acid.	Haemo.ysis.
1 in 40	0.8 c.c.	1 in 200	++
1 in 80	0.8 c.c.	1 in 400	+
1 in 120	0.8 c.c.	1 in 600	0
1 in 160	0.8 c.c.	1 in 800	0
1 in 200	0.8 c.c.	1 in 1000	0
Saline control	0.8 c.c.	—	0

From the *in vitro* experiments it appeared probable that if a concentration of 1 in 400 of sarcocactic acid could be brought about in the blood of an animal haemolysis would result. Laemmous quantities of sarcocactic acid are produced in the animal body by exertion, but it is extremely difficult to approach such quantities by means of injection. The difficulty is that if strong solutions are injected there is a risk of killing the animal, if, on the other hand, dilute solutions are used, the bulk of the injection is so great that the process takes a long time to complete and the necessary haemolytic concentration is not attained. Table III shows the results of intravenous injections of various amounts and strengths of lactic acid, we have omitted three rabbits, two of which died immediately after intravenous injections of very strong solutions, while the other had haemoglobinuria after two injections, of which an uncertain amount was introduced into the vein, the rest passing subcutaneously. In none of the animals included in the table was any serious after-effect noted.

TABLE III—Showing the Results of Intravenous Injection of Sarcocactic Acid

Animal used	Strength of Sarcocactic Acid.	Total volume injected.	Result.
Rabbit	5%	8.0 c.c.	Haemoglobinuria
Rabbit	4%	20.0 c.c.	Haemoglobinuria
Rabbit	3%	20.0 c.c.	Haemoglobinaemia
Dog	2%	26.5 c.c.	Nil
Rabbit	2%	20.0 c.c.	Slight haemoglobinaemia
Rabbit	2%	20.0 c.c.	Nil
Rabbit	2%	100.0 c.c.	Haemoglobinaemia
Rabbit	2%	9.0 c.c.	Haemoglobinaemia
Rabbit	1%	10.0 c.c.	Nil

In those cases where haemoglobinaemia alone resulted the hands of oxyhaemoglobin were found on spectroscopic examination. In the two rabbits in which haemoglobinuria developed the urine was alkaline, dark reddish-brown in colour, and contained a dark granular deposit, bands of oxyhaemoglobin were present. It will be observed in Table III that the injection of 100 c.c. of 2 per cent strength resulted in haemoglobinaemia only, whereas the injection of 20 c.c. of 4 per cent strength produced haemoglobinuria. We have evidence that the haemolysis in this last animal was not produced to any extent by the solution acting in its original strength. The evidence is derived from *in vitro* experiments which showed that this strength of acid, acting on different volumes of blood, produced different results according to the final concentration. When this was greater than 1 per cent oxyhaemoglobin was not formed, while when haemolysis ensued at weaker

concentrations oxyhaemoglobin was liberated. As from *in vitro* experiments the haemolytic titre was 1 in 400, or 0.25 per cent, it appears probable that the concentration of acid which was responsible for the haemolysis in the rabbits lay between 0.25 per cent and 1 per cent. Thus sarcocactic acid is haemolytic *in vitro*, and *in vivo* produces haemoglobinaemia and haemoglobinuria when injected in concentrations well borne by animals.

To summarize our results so far, we have shown that there exists between blackwater fever and certain allied conditions the common factor of deficient oxygenation. We have illustrated how this deficient oxygenation gives rise to the production of lactic acid, and finally we have shown that lactic acid is haemolytic *in vitro* and *in vivo* in doses well borne by the animals.

SUGGESTED CAUSE OF THE HAEMOLYSIS IN BLACKWATER FEVER

The foregoing facts make it probable that lactic acid is the haemolytic agent responsible for the production of blackwater fever as well as for certain allied haemoglobinurias. The anaemia produced by chronic malignant malaria, the stasis in the circulation of such an organ as the spleen brought about by the agglutination of parasitized red cells, and the frequently observed venous thrombosis result in a considerable degree of local anoxaemia and lactic acid accumulation. Very relevant in this connexion is the haemolysis observed by Pansky¹⁷ in the spleens of normal dogs three hours after ligation of the splenic vein.

If we now find that the main exciting causes of blackwater fever are such as will produce contraction of the spleen, already enlarged in volume and choked with parasitized red cells, we may conclude that the circulation in the spleen will be thereby still further impeded and that the local anoxaemia will be increased.

LACTIC ACID IN RELATION TO THE EXCITING CAUSES OF BLACKWATER FEVER

The best record which we have obtained of the exciting causes in a long series of blackwater fever cases occurs in the medical and sanitary reports of the Protectorate of Uganda for the years 1919 to 1924. In the total of 377 cases of blackwater fever, no fewer than 214, or 55 per cent, were precipitated by either exertion or chill or by both combined. Now Bancroft¹⁸ has shown that the spleen contracts on exercise, even mild exercise reducing the size of the healthy spleen to one-half, while severe exercise causes it to contract to one-sixth of its normal volume. Secretion of adrenaline also causes it to contract, and for this reason we have a contraction in chill comparable to that which results from exercise. Hoskins and Lee Gunning¹⁹ showed that adrenaline causes a brief dilatation followed by contraction of the spleen, and the work of Cramer²⁰ proved that exposure to cold is a powerful stimulus to the adrenal gland. The commonest exciting causes of blackwater fever are therefore exertion and chill, and each of these produces marked contraction of the spleen. Quinine is another exciting cause, and, according to the Uganda publication referred to above, it, either alone or in combination with some other factor, precipitated the disease in 41, or 13 per cent, of the cases. In many of the quinine attacks it is not easy to exclude some other exciting cause, such as exertion or chill, these additional causes are, however, excluded in certain cases. Thomson²¹ describes those which, whilst in hospital repeatedly developed blackwater fever after quinine. Here the quinine concentration obtained in the blood could never be sufficient to exert a direct haemolytic action, the maximum concentration of quinine in the blood found by Ramsden, Lipkin, and Whitley²² after oral administration of large doses was 1 in 60,000 and *in vitro* very much greater concentrations than this have absolutely no haemolytic effect. What is evident, however, is that the drug, though non-haemolytic, would still exert its physiological action, demonstrated by Roth²³ of causing active contraction of the spleen. The chief exciting causes of this fever—namely, exertion, chill, and quinine—have, therefore, this action in common, that they cause contraction of the spleen. The contraction of the spleen on

agglutinated masses of parasitized red cells accentuates, as we have said, the local anaemia, further production of lactic acid necessarily follows, especially on exertion, and finally the local concentration reaches such a level that haemolysis occurs. Leakage of haemoglobin into the portal circulation results as soon as haemolysis commences, and becomes pronounced when the circulation through the spleen is re-established.

We have described the conditions leading up to the haemoglobinuria of blackwater fever as occurring in the spleen, and probably in the majority of attacks this is correct. As evidence in favour of this being the case we may quote the following observations. Christophers and Bentley⁴ noted that in all their twenty-seven cases of blackwater fever splenic enlargement was present, Barratt and Yorke⁵ found that in their sixteen cases whose record of the size of the spleen was kept, enlargement was present in fifteen, one case having a barely recognizable degree of haemoglobinuria without appreciable splenic enlargement, Thomson⁶ observed marked enlargement of the spleen in all the eight cases which were examined *post mortem*. Barratt and Yorke further make the following significant statement: "The illness was severe in those attacks in which the enlargement of the spleen was greatest, in those in which enlargement was slight or not appreciable the attack may be described as mild, except in one case." The patient in this case died seven days after haemoglobinuria had ceased. That a similar process may go on in other organs is, however, probable, we have already mentioned the massive infection of the placenta in endemic areas where *P. falciparum* occurs. During labour the contractions of the uterus acting on vessels choked with sporulating parasites increase the existing local anaemia and prevent the oxidation of the lactic acid formed. For this reason haemoglobinuria during or as a result of labour might be expected to occur more readily in European women in an endemic area who have had chronic infection with malignant malarial parasites. In such cases where the taking of quinine has been very irregular or avoided entirely, the parasites multiply freely, the anaemia becomes progressively greater, and the spleen enlarges. Labour itself, with the excessive muscular contraction and exertion, acts as the exciting cause, in these cases a certain proportion of the haemoglobin to be disposed of is probably liberated in the uterine vessels. Thomson⁷ gives records which are of great interest in this connexion, he notes that of the nine cases of blackwater observed by him in which no quinine had been taken, no fewer than five were precipitated by childbirth.

CLINICAL CONSIDERATIONS IN BLACKWATER FEVER

1 *Typical Blackwater Fever*—The mechanism of this has been described above.

2 *Quinine Haemoglobinuria*—This is a condition in which a dose of quinine, whatever the amount, will with some certainty induce a transient attack of haemoglobinuria in a susceptible person, there are innumerable records of this in the literature.

3 *Transient Haemoglobinuria following a Chill or Exertion*—Parsons and Forbes⁸ give their observations on forty-six cases of blackwater fever, they noted that the majority of cases presented a very transient haemoglobinuria following exposure to cold or fatigue. These conditions of transient haemoglobinuria due to quinine, chill, or exertion could all be produced by the contraction of a spleen in which haemolysis had been slowly taking place, with the consequent expulsion of the contained haemoglobin into the circulation, from which it is quickly eliminated.

We may distinguish from typical blackwater fever, in mechanism if not in results, those occasional cases in which numerous parasites are present in the blood throughout the attacks. The continued presence of large numbers of parasites in itself suggests a mechanism somewhat different from that which occurs normally in blackwater fever. The most probable explanation of the haemoglobinuria in such cases is that it is largely due to direct destruction of infected red cells by the parasite during schizogony, a condition comparable rather with pro-

plasmiosis of dogs than blackwater fever in man. Such a form of haemoglobinuria might occur equally well in infection with other forms of malarial parasite.

SOME PROBLEMS IN CONNECTION WITH BLACKWATER FEVER

1 *The Length of Residence*—Much difficulty has been experienced in giving an explanation to account for the period which elapses before the first attack of blackwater fever comes on, and also for the relative immunity which seems to develop after some years' residence in the endemic areas. Table IV is an extract from a table given by Stephens⁹ showing that the majority of attacks occur after six months' residence and before the end of five years' residence.

TABLE IV—Showing the Effect of Length of Residence on the Onset of Blackwater Fever

Length of Residence	No. of Cases	Per cent.
Six months	76	7.2
One year	224	21.3
Two years	346	33.0
Three years	261	24.9
Four years	102	9.7
Five years	42	4.0
Later	75	7.1

As regards the relative freedom from attack in the first six months we believe that the explanation is to be found in the length of time which is required before the malarial parasite usually produces a marked degree of anaemia, and also in the length of time that it takes for the spleen to enlarge. If our theory of the common mechanism of blackwater fever is correct, we should not anticipate that the contraction of a small spleen would result in the expulsion of sufficient free haemoglobin to cause haemoglobinuria. During the pre-blackwater fever period, however, it is probable that many sublethal attacks occur. As regards the relative freedom in after years, it may be explained on the ground that after several years of chronic malaria the spleen becomes fibrosed, and, in this state, is less capable of contraction, this, together with the acquired tolerance to the malarial parasite, would explain the relative immunity of old residents in an endemic area.

2 *The Danger of Moving Blackwater Fever Cases*—It has long been recognized that there is a grave risk in moving a case of blackwater fever even with all possible precautions, and even for short journeys, no satisfactory reason for this has been offered. It appears to us that an explanation is available as a result of our observations recorded above. The blackwater fever patient is extremely anaemic, and has already had a sufficient degree of anaemia to result in haemolysis, he will, especially if he is suffering from pain, make the greatest possible efforts to avoid the discomfort to which he is subjected in transit, and in so doing he will contract his muscles continually, thus producing lactic acid in amounts which cannot be properly oxidized. It is to this lactic acid production that we attribute the relapses which occur so frequently when blackwater fever patients are moved.

3 *Jaundice in Blackwater Fever*—The occurrence of early and often intense jaundice of a degree such as does not appear in paroxysmal haemoglobinuria, nor after the injection of even large quantities of haemoglobin into animals, can be explained by the site of the injection, or of the haemolysis. In blackwater fever the haemoglobin is usually delivered directly into the portal system, and thus reaches the liver in a concentrated form, whereas in paroxysmal and experimental haemoglobinuria the haemoglobin is liberated in the peripheral blood and is considerably diluted before reaching the liver. Pearce and others¹⁰ have shown experimentally that the injection of haemoglobin into the portal system produces less frequent and less marked haemoglobinuria coupled with more frequent and intense jaundice than a similar injection into a systemic vein, the site of haemolysis is therefore the important factor in the production of jaundice in blackwater fever.

SUMMARY

1 Points of resemblance between blackwater fever and certain other haemoglobinurias and haemoglobinaemias are indicated.

2 These points include the presence of an anaemic state, and a resultant increase in sarcolactic acid either locally or generally

3 We produce evidence from experiments, both *in vitro* and *in vivo*, that sarcolactic acid is haemolytic—in the former case to whole human blood, and in the latter to whole animal blood

4 Intravenous injections of sarcolactic acid into rabbits have produced haemoglobinuria and haemoglobinuria, followed by recovery of the animals

5 On the evidence brought forward by us, we conclude that sarcolactic acid is the causal agent in the production of the haemolysis in blackwater fever and these haemoglobinurias

6 The etiology of various types, symptoms, and complications of blackwater fever is discussed in the light of this mechanism

THE GUILLOTINE AND ETHYL CHLORIDE

TEAM WORK FOR THE REMOVAL OF TONSILS
AND ADENOIDS

BY

G. R. SANDIFORD, M.D., CH.B. VICT., F.R.C.S. ED.,

ASSISTANT EUROPEAN THROAT HOSPITAL, GOLDEN SQUARE ASSISTANT TO
AURAL EUROPEAN QUEEN MARY'S HOSPITAL STRATFORD ASSISTANT
AURAL EUROPEAN TO THE LONDON COUNTY COUNCIL,

AND

J. C. CLAYTON, M.R.C.S., L.R.C.P.,

ANÆSTHETIST CHARING CROSS HOSPITAL ROYAL EAR HOSPITAL (UNIVERSITY
COLLEGE HOSPITAL), AND QUEEN MARY'S HOSPITAL STRATFORD

The following observations and description of methods for the removal of the tonsils (with the guillotine) and of adenoids (with the curette) are based on experience gathered from 13 500 cases operated on at Queen Mary's Hospital, Stratford.

The ages of the majority of the patients ranged from 1 to 15 years. The operations were performed by special team work in sessions of twenty-five to thirty patients, and the method has permitted of thirty patients being operated on in one hour. The efficiency of this team work necessitated two operating tables and a movable instrument table, four sets of instruments at least, a sister, a nurse, and a porter who is experienced in carrying in the theatre, one nurse in the waiting room, two nurses in the recovery room for the first twenty cases, with an additional nurse for every ten extra cases or part of ten.

Ethyl chloride was used in the entire series of cases, except for an occasional open ether for instructional purposes in operating. There has been one death. The patient, a girl of 19, was acutely poisoned by the ethyl chloride at the commencement of induction.

For descriptive purposes our observations will be made under the headings Pre-operative, Operative, and Post-operative.

PRE-OPERATIVE CONSIDERATIONS

Cases for operation are divisible into those with definite indications and those with indefinite indications.

Cases with Definite Indications—These are the ordinary textbook cases discharging ears, due to tympanic infection only, not complicated by attic disease, chronic mastoiditis, granular mucous membrane in the middle ear, aural polypus, enlarged tonsillar gland which is found at the anterior border of the sterno-mastoid about half an inch below a line drawn backwards along the lower border of the jaw, attacks of earache, deafness, frequent colds, snoring, and mouth breathing. The adenoid facies is becoming a rarity, and rightly, because its development signifies that the case has waited too long and changes have occurred in the shape of the palate, which becomes raised in the form of a high arch, thus causing deformity of the nasal septum above and crowding of the teeth below. Even in infants up to 6 months of age an indication that the adenoid tissue in the nasopharynx is excessive in amount is given by the state of the hair at the back of the head. The anaemia produced causes restlessness during sleep, as a result the hair is often worn off the occipital region, leaving a thin patch.

Cases with Indefinite Indications—Many children are sent up for operation because they are not sufficiently bright, or they are not putting on weight, or they are too sallow and hollow-eyed.

Acute Tonsillitis—In order to increase the percentage of tonsils completely enucleated by guillotine it is advisable not to operate within one month of an acute attack of tonsillitis, and preferably not for six to eight weeks. The amount of induration at the base of the tonsils is such as to make this region so ligneous that great difficulty arises in dislocating a tonsil from its bed, a process essential for its complete removal.

Nasal Diphtheria—When examining large numbers of children nasal diphtheria is occasionally observed, usually in cases least expected. One case seen with a typical membranous rhinitis was brought up because the boy had been hit on the nose with a football the week before. One point in aid of diagnosis of this disease is that with few exceptions a florid red excoriated area of skin can be seen on the upper lip close to the columella of the septum. A typical membranous rhinitis is less common than an acute catarrhal rhinitis plus this excoriated area.

Patients selected for operation are given a list of instructions to follow, preparatory to operation and on the morning of operation the temperature is taken, the urine examined, and the chest auscultated. The urines are tested for albumin and sugar in groups of five, individual testing being carried out where any group shows a positive. About 6 or 7 per cent of children show some transitory albuminuria, which may possibly be due to the preparatory starvation.

OPERATIVE TECHNIQUE

The Anaesthetic

As already stated, ethyl chloride was used except in a very few cases. Throughout the whole series the same inhaler was used, and the same brand of anaesthetic as supplied by Messrs Duncan Flockhart. The one thing materially altered after the first few hundred cases was the method of administration.

The inhaler employed is called the 'Queen's'. It was first used at the Queen's Hospital for Children, Hackney Road. It consists of a rubber bag an L-shaped junction and a facepiece. A strong red rubber bag is preferred for its durability and economy. The L-shaped junction has a movable device which permits of an easy regulation of air and anaesthetic and is situated on the upper surface of the horizontal limb of the junction. Close to it but nearer the bag is the mouth of a tube which carries the ethyl chloride into the rubber bag where it is soaked up by a swab of gauze held in forceps at the end of the tube. This soaked gauze is prevented from damaging the rubber bag by a wire cage. The

mouth of the tube is closed by a thumbscrew with a coarse thread.

The mask is fixed to the vertical hub of the junction. A celluloid mask with a pneumatic rubber facemask is the best but the latter should be solutioned on to the celluloid. This is important because should the facemask become slack the air which will enter between it and the celluloid will materially affect the anaesthesia. When the gag is in position an can best be excluded by leaving the pneumatic cushion very slack or empty. A series of three sizes of masks is necessary to range from the infant to the adult.

The Doyen type of gag with a good ratchet which can be easily released is found the most satisfactory. A quick release is necessary, so that the release of the ratchet and removal of the gag can be done almost simultaneously at the end of the operation. The gag which has been found most suitable although still rather weak in its spring is the children's size Doyen as supplied by Messrs. Mayer and Phelps. This gag has such good jaw range that it can be used as well for adults as for children.

The old airless method of induction, which was employed in the first few hundred cases, where the air was not once cut off and the induction concluded with stertor and dilated pupils, was soon superseded by a method with improved oxygenation, producing a better anaesthesia with no stertor, and where dilated pupils were looked upon as a danger point. With the old method artificial respiration and administration of oxygen were found necessary in about 10 per cent of cases, whereas with the later method recovery is practically devoid of anxiety. With this more advanced method the quantity of anaesthetic agent required becomes greater.

Commencing with a patient from 1 to 3 years of age an initial dose of 10 c.c.m. may be squirted down the tube. It is often found that this initial dose is inadequate to produce anaesthesia in a satisfactory time owing to the fact that a great deal of the anaesthetic is absorbed by the gauze and some by the rubber, and also that the bag and inhaler have not become sufficiently heated by the exhalations of the patient and the manipulation by the anaesthetist. A further 5 c.c.m. may be given for each child ranging from 3 to 7 years for the following eight to ten patients. After this the dose can be reduced to 4 c.c.m. or even 3 c.c.m., until the ages of the patients begin to rise again to 11, 12, and 13, when a return to 5 c.c.m. will be necessary and even again to 10 c.c.m. if the age increases to 16. So it is obvious that in a session of thirty children they should be brought in for operation in regular order from the youngest to the oldest.

The patient is placed on his back and the gag is inserted between the left lateral incisor teeth. This position gives the best scope to the surgeon. The mask is slipped over the face so as to exclude entry of air beneath it; the air regulator of the inhaler is steadily closed, but not entirely, a slit the thickness of a visiting card being always left.

The two most important items to watch now are *breathing* and *colour*. The breathing may at first be rapid and irregular, or the breath temporarily held, but this alters with advancement towards induction. The colour will at once become heightened, and should remain so throughout the anaesthesia.

When the breathing has become regular and deep, the jaw relaxed (ascertained by opening the gag) and no palpebral reflex is observed when blowing on the eyelids, then the patient is ready for operation. In a very small proportion of cases the patient is ready for operation although the relaxation of the jaw is not complete and although the breathing is regular and deep and there is no palpebral reflex. In such cases the anaesthetic should not be pushed, or an overdose will result, and force will have to be used, either by the anaesthetist bringing his right hand into action to assist his left hand or, preferably, by obtaining the assistance of the surgeon to open the jaw.

Difficulty in opening the jaw is experienced when the patient's under lip is misplaced between the gag and the lower teeth. This is due to the anaesthetist failing to hold the patient's lower teeth tightly against the gag during induction. Should this happen it is as well quickly to release the gag and free the lip, as much to save the lip from injury as to anticipate a difficulty in respiration which occasionally occurs, attributable to this cause.

With the signs of completed induction as stated above the pupils will usually be found contracted, or if with a slight tendency to dilatation they will contract rapidly to light. This stage of the proceedings is most important, the most urgent necessity is for the patient immediately to begin eliminating the anaesthetic by expiration, and continue to do so. Anything that impedes this elimination before the return of the reflexes means that the anaesthesia will get gradually deeper instead of lighter. Therefore it is important to realize the various ways in which the respirations can be impeded, in their order of occurrence.

The first respiratory difficulty may show itself at the very commencement of induction in cases where the tonsils are

meeting in the mid line. In these cases induction has to be convoked, and because elimination of the anaesthetic is obstructed a little anaesthetic will produce induction.

The next obstruction arises when the patient voluntarily holds the breath and then takes a sudden deep breath, for then the vapour is concentrated too suddenly. The effect is the same. A laryngeal spasm is set up, causing coughing where the breath is still held, and again the anaesthetic is prevented from being eliminated, so the patient will go quite deeply under with a small quantity of anaesthetic.

The third difficulty occurs in some patients when the jaw is extended by the gag. If this happens there should be time to remove the tonsils and turn the patient on the right side, but then the gag should at once be released until colour is again good and respirations steady, when the gag can be again opened and the adenoids removed. Each part of the operation will take from eight to ten seconds, which is the limit of time that the patient should be left with obstructed respiration. With a well timed anaesthetic the patient should cry, cough, or struggle on removal of the gag.

Blood will be the fourth obstruction, and even at the end of the operation, although elimination of the anaesthetic has occurred satisfactorily the whole time, the patient will often go quite deeply under again although on the verge of the return of reflexes. This is an obstruction found mostly in young children, and is easily remedied by holding the child's legs well up to effect good gravity drainage and stimulating with a douche of cold water. Sometimes a swab on a holder may be found necessary to remove clots.

Occasionally a large flabby tongue will cause obstruction. No obstruction has ever been found due to a mass of adenoid tissue finding its way into the larynx.

Two points have emerged from observations during this series of cases. (1) When trouble occurs with ethyl chloride anaesthesia it shows itself first in the respiration. (2) In nine cases out of ten it is due not to the toxic effect of the ethyl chloride or to an initial overdose, but to some mechanical factor preventing elimination. Patients should not be removed from the table until the colour is good, and crying, coughing, or struggling has taken place. Salivation is quite rare, but undoubtedly the secretion set up by acute catarrhal conditions will be greatly increased, and if excessive will cause respiratory obstruction. This is why operation is well postponed, especially when young children are affected with acute catarrhal conditions, until the symptoms have subsided.

From the point of view of team work, and time, it is interesting to note that induction, timed over a series of cases, takes from thirty-five to forty seconds, and that this, added to a similar average period for the operation of from fifteen to twenty seconds, gives an approximate inclusive time of about sixty seconds. Another sixty seconds should suffice for the patient to be brought in and laid on the table, including also the return of reflexes and removal to the recovery room, showing the possibility of operating at the rate of thirty patients to the hour.

For such efficient team work it is necessary for the anaesthetist to assist the surgeon in his operating. To do this the anaesthetist's first action is to slip the inhaler into his lap. Then, with the patient on the back, to assist in the removal of the tonsils he should hold the head firmly between his two hands with the tips of the left fingers steadying the gag, the head being held at the most convenient angle for the surgeon.

As the surgeon is evulsing the tonsil the head can be turned either to the right or left to assist this manoeuvre. The patient being turned on the right side, his head is supported in the palm of the anaesthetist's right hand, leaving the occiput free for the left hand of the surgeon. The anaesthetist's left hand steadies the gag and is ready to release and remove it at the termination of the operation, when the head of the patient is handed over to the nurse. A point in technique at this stage which saves considerable time is to ensure that the nurse who is holding the kidney receiver against the patient's cheek, when the latter is on the side, shall press the receiver firmly against the cheek just above the anaesthetist's thumb. By doing this and receiving the patient's head promptly, the anaesthetist's hands are kept free from blood, thus avoiding the necessity of washing between each case.

Although the foregoing description with its detailed observations would lead some to consider that ethyl chloride was a difficult and dangerous anaesthetic to administer, it

must be remembered that whenever a detailed account of any act is written it invariably seems to make that act appear more complicated than it really is. The evidence over this large number of 13,500 cases shows that ethyl chloride may be looked upon as a safe agent for anaesthesia where the surgeon and anaesthetist work in unison. Also, where numbers of patients have to be dealt with and a quick recovery is necessary and the patients are to be sent home at the earliest possible time, ethyl chloride is certainly the anaesthetic to meet the circumstances, although it is more suitable for children up to 16 years than for adults. It is found that with the latter, although induction is quite easy, recovery is accompanied by a great deal of mental agitation and struggling. Children are also much brighter and fitter on the day after operation when ethyl chloride has been given than when ether has been administered. On the other hand, ethyl chloride is not the best anaesthetic for instruction in operating.

The Operation

It is essential that a good source either of daylight or artificial light is so placed and so extensive in origin that the surgeon can work between the patient and the source of light without a shadow being cast. A table two or three inches too high is sufficient to interfere with the exactness of the most experienced surgeon.

Removal of Tonsils.—The guillotines used are Heath's reinforced Mackenzie pattern (blunted) in three sizes, and the removal is done by a continuous movement which resolves itself into

- (a) Lift up the tonsil with the guillotine
- (b) Push out the tonsil with the guillotine
- (c) Push in the tonsil with the thumb or index finger of the opposing hand
- (d) Shut home the blade with the thumb as much as possible
- (e) Completely shut home the blade by adding the pressure of the other thumb
- (f) Roll the guillotine outwards

Bigelow epitomized the movements necessary for the reduction of a dislocated hip thus "Lift up, bend out, roll out," and his words might be paraphrased for the technique of tonsillectomy as follows "Lift up, push out, push in, roll out." An unusually fibrous tonsil may be helped from its bed during the last rolling movement by running the index finger of the free hand round the back of the guillotine and rapidly dissecting with the finger. This is better than using scissors at this stage, as scissors usually cut away some of the posterior pillar which has been twisted forwards.

Removal of Adenoids.—This is very often done imperfectly. The instruments preferred are Jenkins's curette for the main mass, Beckmann's baby unguarded for the lateral pads, Seymour-Jones's tag forceps. Curettes should be very sharp and of two sizes—a large guarded curette for the removal of the main central mass, and a small unguarded curette which can feel its way into the lateral recesses and remove all the remaining adenoid tissue with one cut on each side. With the former a steady strong pressure is exercised, with the latter a much gentler force. By this means a complete removal is invariably effected and adenoid tags seldom left. After a time the surgeon can become expert in palpating with a curette, so that the amount of adenoid tissue removed can be estimated before the curette leaves the post-nasal space, and any deficiency below this be sought for in the form of a tag. To such an extent is this the case that the anaesthetist, who is holding the patient's head, can by transmitted impulse also feel what is happening in the post-nasal space, and be ready to register surprise when the "bag" falls below his estimate.

POST-OPERATIVE CARE

On completion of the operation, should the patient show no return of consciousness, as evinced by crying, coughing, opening of the eyes, or struggling, a stimulus is useful in the form of iced water, which is allowed to splash on to the face from the height of a foot or so. While this is being done the nurse, who is supporting the patient's head, should close the left auditory meatus with a finger.

Method of Carrying and Holding Patient

The porter plays a most important part in the technique of the team work, not only by holding and turning the patient, but also by removing the patient to the recovery room in such a way that all risk of respiratory obstruction from blood clot is reduced to a minimum. These manoeuvres require rather careful studying. During induction the patient's wrists are held lightly by the side of the hips, and this is continued until the completion of the removal of the tonsils (Fig 1). During

FIG 1

removal of adenoids, the patient having been turned on to the right side, the porter still continues to hold the patient's right wrist with his left hand, so that his left arm is encircling the patient's hips and his left hand is under the patient's right buttock. In his free hand the porter holds a towel in readiness for the removal from the table (Fig 2). Passing his right hand

FIG 2

with the towel under the patient's head to the side of the mouth, and raising the body with the left arm encircling the hips he carries the patient into the recovery room with the buttocks tucked well up into the porter's left axilla and the head resting face downward in the porter's right hand at a much lower level than the hips (Fig 3).

FIG 3.

After recovery is complete the patient is allowed to take the position of election, some lying down, others sitting up. Most children vomit some time after recovery, but this is almost always caused by the blood swallowed. Children can be sent home three hours after operation, except in those cases where the pulse is found to be poor, when it is safer to wait a little longer, or even to admit for the night where possible, or, if impossible, to remove home with

special care. It may be mentioned that a feeble pulse after recovery is more often found in patients of feeble or depleted physique, and would seem to be due more to this than to operation shock or effects of the anaesthetic.

Haemorrhage, Immediate and Late

If bleeding is considered to be brisker than usual it is a matter of experience that in the large majority of cases it will cease rapidly if nothing is done. It is rarely necessary to hold a piece of gauze in the tonsillar bed, but this manoeuvre will control those cases which do not cease.

With regard to late haemorrhage, the source of the bleeding must be looked for. Generally it is coming from the post-nasal space, and frequency of occurrence varies inversely with the sharpness of the adenoid curette, just as the frequency of tonsillar haemorrhage varies inversely with the bluntness of the guillotine. The treatment is to spray the post-nasal space with cold hydrogen peroxide (vols 10) through the nose with an atomizer. If this fails, run the end of the index finger round the post-nasal space either to dislodge clots, which may be holding a vessel open, or to remove a half-detached tag. If the bleeding is from a tonsillar bed, apply pressure by means of a pad of gauze on a holder. Press gently at first, and increase the pressure gradually as the pharynx becomes used to the presence of a foreign body. If this fails, hydrogen peroxide (vols 10) on gauze can be tried. Failing this, oil of turpentine can be used on gauze, combined with horse serum or haemostatic serum, intramuscularly. As a last resort, which in this series of cases has had to be used on one occasion only, a general anaesthetic must be administered and the bleeding point ligatured.

Points in After-treatment

(1) It is important to encourage the patient to eat and drink on the day following operation if possible. The throat is cleaned up by the muscular contractions involved thereby far more quickly than by any other method.

(2) It is very important to keep the bowels open.

(3) A shawl fastened around the head, which at the same time keeps the neck warm, is very comforting, especially when the glands of the neck are painful or caruncle develops.

(4) Enaechie is divisible into (a) that immediately following operation, and (b) that occurring after a lapse of twenty-four hours. The former is due to some reflex nerve pain and the latter to infection. For both warmth is essential, and for the latter the further appropriate treatment.

A NOTE ON ECLAMPSIA

WITH REPORT OF A COMPLETE POST-MORTEM EXAMINATION

BY

BETHEL SOLOMONS, M.D., F.R.C.P.I.,

MASTER

AND

F. S. BOURKE, L.R.C.P. AND S.I.,

PATHOLOGIST, ROTUNDA HOSPITAL.

DURING the year 1926-27 there were twelve cases of eclampsia in the Rotunda Hospital, with two deaths. In addition, there were 381 cases of albuminuria without death. Details of these are given in the annual report. We stated in this report that it is difficult to compare statistics of the present with those of the past when antenatal care was not customary, for we believe that many severe examples of present-day eclampsia would have been true eclampsies in the past. From March, 1927, until April, 1928, there was no eclamptic death in the hospital, and we hoped that we had finished with mortality. This was not to be, and the full notes of a fatal case are appended. The cases which we encounter nowadays are of marked severity. One of the two deaths in our last report occurred three and a half days after the woman had recovered from eclampsia, and the eclamptic toxin could not be held altogether responsible. In twenty-two cases since November, 1926, there were altogether three deaths—that is 13.6 per cent., a percentage on which, with our treatment, it is possible to improve. If a woman has had

a fit and albumin is present she is included in the eclampsia statistics.

There are several features of interest in the fatal case under review, the most marked being that the *post mortem* examination showed how impossible it was to achieve a successful result.

Case History

A primipara aged 24 was delivered spontaneously of a live child two hours after admission to the hospital. She had never attended the antenatal department and there was no history of previous illness. Routine examination of the urine revealed the presence of solid albumin. There was slight oedema. She vomited house mixture. The routine eclampsia treatment was given. Glucose was taken by the mouth. The result of colon lavage was never satisfactory (and a good result usually means a good prognosis). The first fit occurred six and a half hours after delivery, and there were eight fits altogether. There was a good deal of facial twitching. Three and a half hours before she died respirations ceased, the pulse continued comparatively good in tone and volume. In spite of continued efforts at artificial respiration (chiefly mouth-to-mouth) for three and a half hours she died. The other usual restorative measures—for example oxygen, lobeline, etc.—were also resorted to.

We have never seen a case quite like this, we have often succeeded in resuscitating eclamptics apparently dead by clearing out the mucus from the throat, artificial respiration, oxygen, etc., but our efforts here were futile.

We were fortunate in being able to obtain a complete *post-mortem* examination, the result of which was as follows.

Findings at Necropsy

The body was well nourished and fully developed, no marked oedema was present. When the abdomen was opened the uterus presented the usual post partum appearance, it was normal in size, shape and position. The adnexa were normal.

Liver—The liver was enlarged and weighed 1.878 kilograms (normal 1.2 to 1.4 kg). Extensive subcapsular haemorrhages were most marked on the superior surface of the right lobe, and smaller areas were scattered all over the entire surface. On section macroscopically the areas of haemorrhage were seen to be sprinkled evenly through the organ giving an appearance of advanced nutmeg liver; the remaining liver tissue was of a pale buff colour. Microscopically the areas of haemorrhage were seen to be mainly in the periportal region of the liver lobule. In many lobules there was marked fatty degeneration of the liver cells in this region; there was also some haemorrhage in the centre of some of the lobules. The liver cells generally showed cloudy swelling, and in many of them the nuclei were undergoing karyolysis. Here and there through the section were seen vascular areas, probably haemangiomas. According to McCallum the poison of eclampsia destroys the cells of the liver lobule nearest the portal vein, and the scattered areas of haemorrhage correspond with the areas of necrosis around the periportal region. This agrees with our findings in this case. According to Schmorl the liver necrosis is due to syncytial masses swept from the placenta into the liver veins, but we have not found any evidence of syncytial tissue in our sections of the liver.

Gall bladder—Bile-stained, nothing abnormal.

Kidneys—Weighed approximately 112 grams each; they were slightly enlarged, but the relationship of cortex to medulla appeared normal. The capsule stripped readily off both. The surface was covered with small subcapsular haemorrhages giving an appearance resembling flea bitten kidney. Microscopically, there was much cloudy swelling and fatty degeneration of the renal epithelium; the vasa recta were congested, and there were some extravasations of blood in their vicinity. The glomeruli presented no marked abnormality, except that in some places there was seen a wide separation of Bowman's capsule. There was no evidence of haemorrhage in this region according to some observers the primary renal lesion is a degeneration of the walls of the glomerular capillaries but this was not manifest here (McCallum merely mentions that necrosis of the renal epithelium is sometimes found in eclampsia).

The ureters presented no marked abnormality to the naked eye. The bladder was distended and thin walled; it contained approximately five ounces of bloody urine.

The spleen was normal.

Stomach—Normal in position and shape. There was an extensive subperitoneal haemorrhage on the anterior and posterior aspects. This was most marked at the cardiac end towards the lesser curvature, it extended downwards about a hand's breadth from the cardio-oesophageal junction and was sharply limited above at this point. The wall was extremely thick and boggy to the touch. On opening into the cavity the entire mucous membrane except for about two fingerbreadths at the pyloric end was blood stained, and the cavity contained about four ounces of dark fluid. There was no food present. A microscopical section of the stomach wall was made in the zone of haemorrhage. The wall was about 1½ cm. thick at this point and a rather extensive area of haemorrhage was found separating the muscularis mucosa from the outer muscle coats. The lining mucosa was markedly oedematous and showed some cloudy swelling.

The duodenum, jejunum and part of the ileum were enormously distended with gas. The distension produced a wide separation of the parallel muscle fibres giving a striated appearance to these parts. The mucosa of the duodenum also showed this dark staining. The ileum in its remaining twelve inches was empty and collapsed.

The caecum ascending transverse, and descending colon, and rectum were also empty and collapsed.

Heart.—The pericardial sac contained about two ounces of blood-stained fluid. The heart showed no abnormality.

The lungs were soft and congested. The condition was most marked at the bases.

The brain showed patchy subdural haemorrhages the largest of which was in extent about the size of a two shilling piece. They were mainly on the superior surface and in the region of the frontal lobes. There was an extensive haemorrhage into both lateral ventricles and into the fourth ventricle. On section three distinct areas of haemorrhage could be seen in the substance of the medulla oblongata.

It will be seen from the above report that the woman was beyond cure, for death was obviously due to paralysis of the respiratory centre in the brain as the result of haemorrhage, and this accounted for the failure which attended our efforts at artificial respiration.

The case provides an example of the necessity for training women to seek ante-natal care, had this been obtained here, a fatal result would have been unlikely. With ante-natal care there should be no deaths from eclampsia.

LOBAR PNEUMONIA AS AN INFECTIOUS DISEASE*

BY

C. H. WHITTLE, M.A., M.D. CAMB., M.R.C.P. LOND.,

CLINICAL PATHOLOGIST, ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

(Ernest Hart Scholar, British Medical Association.)

SOME eighty strains of pneumococci have now been collected, and I have published three papers giving in detail the results of the work up to March, 1928.^{1, 2, 3}

The conclusions arrived at last year⁴ have been amplified and confirmed. Lobar pneumonia, broncho pneumonia, and empyema occurring in previously healthy persons are invariably caused by pneumococci of high virulence, measured by the effect on mice, whereas such conditions as terminal pneumonia and post-operative pneumonia, arising in subjects whose health is already impaired, are commonly caused either by pneumococci of feeble virulence, or by organisms such as *Strep. salivarius*, *M. catarrhalis*, Friedländer's bacillus, etc. The pneumococci of low virulence resemble these catarrhal organisms in other respects, for like them they are frequently the cause of chronic bronchitis, conjunctivitis, nasal catarrh, and other comparatively minor infections of the respiratory tract and of the membranes and sinuses adjoining it. A large proportion of the pneumococcal strains recovered from such conditions set up a chronic, low-grade type of infection in the mouse which may last as long as three weeks and ends in septicaemia. This response is unexpected and differs so completely from the typical septicaemia, which is fatal within forty-eight hours, that it calls for further detailed investigation. A number of mice affected in this way have been collected and are being examined, by serial sections of viscera, etc., in order to discover the nature and site of the lesion.

The pneumococci causing lobar pneumonia or broncho-pneumonia in man have repeatedly been found to produce a parallel lobar pneumonia or broncho-pneumonia in the rabbit when introduced by the trachea. The symptoms, course of the disease, morbid anatomy, and histology in the two species are strikingly similar. In addition, strains of feeble virulence, from cases of terminal pneumonia, bronchitis, etc., have so far failed to produce any sign of pneumonia in the rabbit. Over twenty experiments on rabbits have been performed, but to complete the series a few more strains from lobar pneumonia are required. I am working out the results in detail, in co-operation with Dr. J. F. Gaskell.

There is now evidence, collected from several cases,⁵ that the virulence of pneumococci remains unchanged during the period when they can be recovered from human lesions. At the end of three or four weeks no change was noted in the virulence of the strains recovered. Needless to say, the "type" also remained unchanged. Similar stability has also been noted in a strain recovered from a patient

on three occasions during an attack of bronchitis. Though the intervals between the attacks were as great as eighteen months, the organism isolated in the second and third instance exhibited the same cultural and immunological reactions and possessed the same virulence as the one first isolated. Moreover, on each occasion it was obtained in pure culture. It appears, therefore, that a single strain of pneumococcus can produce recurrent attacks of bronchitis in a suitable subject. Such a subject may be considered peculiarly susceptible to such a strain. Whether each attack is the result of fresh infection, or whether it represents a flaring up of a process which is always smouldering but gives no symptoms, is a question to which no immediate answer can be given.

The important question as to whether the feebly virulent pneumococci are capable of becoming sufficiently virulent to set up pneumonia in a healthy person has also been investigated. Attempts have been made to raise the virulence of some of them by various passage experiments on mice. Though in one case passage inoculations have been continued for over a year, with thirty passages, there was no appreciable increase in the virulence. These results are in marked contrast to the rapid increase in virulence following passage of strains which were originally of high virulence, but which had been allowed to deteriorate, compare Griffith's results.⁶ The pneumococci of feeble virulence, like those of high virulence, therefore present a striking constancy and stability in their virulence.

The serological "type" of the pneumococcus affords little evidence of its power to produce pneumonia save in so far as Type I organisms have all been highly pathogenic, and therefore potentially pneumonic, and Group IV organisms mostly the reverse. The dearth of Type II strains still persists (compare Griffith's statistics for the same period, 1924-27⁷).

CONCLUSIONS

1. Lobar pneumonia and broncho pneumonia arising in previously healthy subjects are caused by pneumococci whose virulence is invariably high.

2. Such minor infections as nasal catarrh, chronic bronchitis, conjunctivitis, etc., may be produced by a pneumococcus, but its virulence is of an altogether different and lower order. Pneumococci of this class are nevertheless able to set up pneumonia in a debilitated subject, though they share this power with a number of other organisms commonly found in the respiratory tract, such as *Strep. salivarius*, *M. catarrhalis*, and Friedländer's bacillus.

3. The first class of pneumococci possess virulence which is stable over considerable periods of time (at least four weeks) *in vivo*, and which is specific to the type of lesion they produce. This class may be regarded as the pneumonia-producing, or pneumonic, type of pneumococcus.

4. The second, or catarrhal, type also possess a stable order of virulence, and their conversion into the pneumonic type has so far proved impossible by the usual methods of passage.

5. All the experimental evidence shows that the pneumonic highly virulent type of pneumococcus is the one responsible for the epidemiological spread of pneumonia, the less virulent catarrhal type is negligible in this respect. The mode of spread is by contact, evidence of which is given in a paper I expect to publish shortly in conjunction with Dr. R. Ellis. The strains of epidemiological importance can be recognized by their high titre of virulence for mice (vide Gaskell, Bradshaw Lecture, 1927). The isolation of persons harbouring in their throats pneumococci of this type is therefore a measure worthy of consideration in attempting to prevent the spread of lobar pneumonia.

I wish to thank Dr. J. F. Gaskell for suggesting the lines of research and for his unflinching help and criticism, and Professor W. E. Dixon for the hospitality of his laboratory and for his help in drawing up this report. I should like too to take the opportunity of expressing my gratitude to the British Medical Association for its generous support.

MEDICAL, SURGICAL, OBSTETRICAL.

MULTIPLE TRAUMATIC ABDOMINAL ANEURYSM

TRAUMATIC aneurysm of the abdominal aorta must be a very rare condition, and the following account of such a case appears, therefore, to have a special interest.

An old man died suddenly one morning when attempting to rise from bed. Some time previously a large abdominal tumour had been found which because of the expansive nature of its pulsation had been diagnosed as an abdominal aneurysm. The manner of his death suggested that this had ruptured and the necropsy proved the assumption to be correct, but this diagnosis was by no means complete. Instead of one aneurysm there were four occupying the whole extent of the abdominal aorta and the greater part of the external and common iliac arteries. The peculiar point was noted that, whereas all the large arteries of the abdomen from the origin of the coeliac axis to the termination of the external iliac arteries on either side, were degenerate, calcified irregularly dilated, and aneurysmal as shown in the accompanying illustration the thoracic aorta and the other large vessels of the body showed only a slight degree of atheroma which might be considered as even less than normal for a man of his age and occupation and it is in the matter of occupation that, to my mind the most interesting facts arise.

By profession the patient had been an acrobat, strong man, and trapeze artist who, in his day, had acquired not

a little fame both in this country and on the Continent. When we consider that almost every day for twenty years this man was spending some time, probably about half an hour, swinging and turning on a hard trapeze and rolling round the instrument on his stomach, we may arrive at a possible, nay, a probable cause of this extraordinary aneurysmal condition of those vessels which, in the process of his acrobatics, would be most exposed to injury. The fact that that part of the aorta which was protected by his thorax was like the normal aorta of a young adult, while the abdominal aorta in the region of the bifurcation and the iliac arteries lying on the pelvic brim were in such a

remarkable state of degeneration, would, to my mind, point to the fact that these aneurysms were directly traumatic in origin.

The patient was a senile dement who, although remarkably grandoise, never showed any signs, clinical or serological, of syphilis in any form. Moreover, there were no post-mortem signs of this disease, and to my mind the aneurysms appear to be of directly traumatic origin.

I know of no case in which such an extensive aneurysmal condition of the abdominal aorta can be associated with direct trauma often repeated over such an extensive period, and I am of the opinion that the situation of the affected vessels where they could be directly crushed between the rigid vertebral column and pelvic brim and the still more rigid trapeze, considered together with the comparative immunity of the more protected vessels, proves conclusively that the cause of the aneurysms was directly traumatic.

I should be interested to learn whether, as regards the abdominal aorta, there are any other such cases on record.

I am obliged to the subcommittee of the Colney Hatch Mental Hospital for permission to publish this case.

INTESTINAL OBSTRUCTION SPONTANEOUS RECOVERY

INSTANCES of spontaneous recovery following intestinal obstruction are sufficiently unusual to merit recording.

The patient was a healthy, well nourished boy aged 9 with a previously uneventful history. On the evening of May 22nd, when

attempting to recover a ball, he squeezed himself through an iron railing, the bars of which were six inches apart. He said he felt a slight pain then over the abdomen but did not tell his parents of this. Next morning he complained of colicky pains in the lower abdomen and vomited. There was no evidence of hernia and no tumour could be felt. The vomiting became very severe, and on May 24th was green with shreds of mucus. The bowels were confined without a passage of flatus. Temperature 99° F., pulse 100. Reflexes normal.

On May 25th there was a slight distension of the abdomen and the vomiting became definitely faecal. A turpentine enema was given with no result. Turpentine enemata were again administered on May 26th and 27th without success. At this stage, owing to the history of traumatism and as the boy's condition was good and there were no marked signs of collapse we decided to "wait and see." On the night of May 27th the vomiting ceased. Flatus was passed, and the pain was much lessened. A good result followed a turpentine enema on the following morning and after this recovery was uneventful.

The condition described above might have been caused by a kinking or a traumatic paresis of the bowel.

Reports of Societies.

CHILD GUIDANCE

At a meeting of the London Association of the Medical Women's Federation on June 26th, with Dr. AMY SIFFINARD in the chair, Dr. LETITIA FAIRFIELD gave an address on child guidance.

Dr. Fairfield said that she had recently investigated the methods used in America for dealing with delinquent and difficult children, and had been greatly impressed. The idea that the chief need of the difficult child was help in adapting itself to its surroundings was not a new one, but the scheme of clinics on a large scale designed to this end dated only from 1908, when a group of women in America, of whom the most prominent was Mrs. Dummer, recognized that the treatment of the juvenile delinquent was unsatisfactory and unscientific. Mrs. Dummer decided to finance a clinic in Chicago under Dr. W. Healy, who found that if the motives of the child delinquent were studied it often became apparent that he was not abnormal or psychopathic. Without careful inquiry it was often impossible to tell whether the child or the environment was responsible for the delinquency. From the failure of the child whose bad conduct had brought it into the hands of the police Dr. Healy worked back to those with lesser degrees of maladaptation, and came to the conclusion that the development of faulty habits might be checked and impulses might be trained in the right direction if the child were studied at an earlier stage. Meanwhile other sociological efforts were being made. Mr. Clifford Beers, who had had an acute attack of insanity in early life and had suffered harsh treatment, resolved to dedicate his life to securing more understanding treatment of the insane. A great society, the National Committee for Mental Hygiene, with branches in all the States, arose from his efforts, and it was again found necessary to work back to early years in order to find the origin of breakdowns in later life. This work had not proceeded on purely Freudian lines, nor had the child guidance movement developed on psycho-analytical principles, though all modern psychology had absorbed something from Freud's ideas. The psycho-biological theories of which Dr. Adolphe Myer of the Johns Hopkins Medical School was the chief exponent had had much influence on the child guidance movement. This conception of conduct was that it represented the reaction between personality and environment. Myer hardly recognized types of mental disease—only types of individuals reacting to different conditions, he made no sharp distinction between the normal and the abnormal, the sane and the insane. It was on these lines that American social work was developing.

Dr. Fairfield proceeded to describe the organization of the child guidance movement, which involved a preliminary inquiry into the record of the child at school and at home, and into the results of the standardized tests for mental ability. It was surprising how often the cause of the difficulty was that the child was being tried beyond its

mental capacity. Sometimes an incorrigible child was merely an overlooked defective. The tests could only be evaluated, however, with reference to the child's emotional reactions. A physical examination was made in the case of each child and was followed by a careful study of its environment by a "psychiatric" social worker, who was trained on the lines of the British Charities Organization Society workers, but with special instruction in psychology and in the mechanism of behaviour. Dr Fairfield pointed out that in America less emphasis was laid on material and more on personal factors. If a social worker in this country found that a child lived in a neat house and had good meals, she reported that he had a good home, if the child did not get on well the inference was that it was due to personal wickedness. No account was taken of a possibility that the mother might nag at the child or quarrel with her husband, in which case the psychological atmosphere would be that of a bad home. In any home one spoilt child might evoke revenge reactions on the part of the others. Since all these factors were reported, the American histories were fuller than those in Great Britain, and this was an advantage. The most important examination of the child was the final one by the trained medical psychiatrist, who had before him the reports from all the other workers. The examination, when completed, usually gave clear indications for treatment for the child of pre-school age or of school age. Children who failed during the period of parental training of the simpler instincts might develop enuresis, bad habits, attacks of bad temper, and persistent and serious food fads. In a certain percentage of cases they were very intractable. The education of teacher and parent in their management was being undertaken in association with kindergarten and nursery schools. For children of school age a "visiting" teacher with the training of a psychiatric social worker acted as adviser to the staff on problems of discipline. She also visited the home and reported to the teacher, and vice versa, acting as a liaison officer. Since these agencies were available to deal with difficult children, only the really intractable cases needed elaborate study in guidance clinics, which dealt with conduct problems and also with retardation in school work. In America the child who did not advance with his class was considered to bring disgrace on himself and on his teacher. Very often the retardation was not a question of intelligence, but of conduct. In other cases the children were naughty because they were mentally dull, and were tried too hard. Dr Fairfield explained that the guidance clinics were under voluntary bodies such as the Commonwealth Fund, or were conducted in connexion with the big hospitals. The Commonwealth Fund, a wealthy organization, had financed nine demonstration clinics, which served also as training centres. One was about to be started in London and would be financed for three years. At the Johns Hopkins Hospital, Dr Esther Richards was in charge of an excellent clinic under the general direction of Dr Myer. The treatment might involve a radical change in the plans for a child's life, and was especially valuable for "dependent" children who were boarded out by voluntary societies in homes which might not be suitable to the individual need without considerable adjustment. The expansion of the movement, both for children and adults, was remarkable. Charitable societies were beginning to establish guidance clinics so also were the great department stores. District nursing associations sometimes paid a psychiatric worker to advise the nurses. This expansion proved the value of guidance clinics more conclusively than any statistics.

Dr MINA DONNIE, in the subsequent discussion, remarked that in England also many dependent children were being boarded out in homes. Dr ALICE HUTCHISON said that in Leytonstone an admirable clinic was in operation but that throughout this country the work was limited by lack of funds. Dr H. MACEAY asked what number of children could be dealt with at any one clinic, this was relevant to the financial aspect of the work. Dr FAIRFIELD, in reply, said that the Cleveland Clinic consisted of three medical practitioners, five social workers, and two or three psychologists, such a team could deal with as many as a thousand cases in a year.

Reviews.

THE EXTRA PHARMACOPOEIA

We have much pleasure in welcoming the nineteenth edition of the first volume of MARTINDALE and WESTCOTT'S *Extra Pharmacopoeia*.¹ It is forty-five years since the first edition appeared, and for nearly half a century this book has maintained its reputation as one of the most useful works of reference that the medical profession possesses. To have maintained a publication of this kind at a uniform high standard throughout such a long period is in itself a remarkable achievement, and the merit of this performance is enhanced by the fact that the number of new drugs that appear each year grows steadily, and hence the work entailed in keeping the volume up to date must correspondingly increase. It is only four years since the last edition appeared, but the index contains more than one hundred names of new drugs and preparations. Inspection of any sample of the thousands of references shows that Dr Harrison Martindale has maintained the well-established reputation of this *vade mecum* by providing a full account of recent work. The labour must be enormous, and it is surprising to learn that the author has also found time to make personal investigations of a large number of drugs.

A reference book of this kind cannot be critical, because no one could have first-hand knowledge of more than a tithe of the thousands of drugs and preparations mentioned. All the author can hope to do is to give a fairly balanced summary of the claims made for drugs and the criticisms made of these claims. The high reputation of this volume gives, however, considerable authority to its pronouncements, and we think the remarks made regarding cocaine are biased in a rather dangerous direction. For example the following quotations are chosen for reproduction in prominent type: "Forty years in the profession and never seen a drug addict" (p. 334), "None of its rivals appears to have any material advantage over cocaine" (p. 342). The following statement of a committee appointed by the American Medical Association (1920) is reproduced in heavy type: "None of the synthetic local anaesthetics equal cocaine when applied to mucous membrane," but a later recommendation of the committee that "Cocaine should not be injected into the submucous tissue or subcutaneously" (*Journ Amer Med Assoc*, 82, 876, 1924) is not mentioned. The author evidently believes that the dangers of cocaine have been exaggerated, and he has a very natural bias in favour of this valuable drug, because the late W. Martindale took a great share in introducing it into medical practice. We think, however, it would have been better if he had made it clearer that his views do not agree with the conclusions of the committees that have investigated the subject. After all, it is a great deal safer to overestimate than to underestimate the dangers of cocaine. We have referred to this point at some length because the well-deserved popularity of this volume gives its opinions a peculiarly wide currency.

The perusal of a new edition of this work is always interesting because it provides an opportunity for estimating the extent and importance of recent advances in therapeutics. The application of hyperthermy to pernicious anaemia is undoubtedly the chief advance that has been made. Another outstanding advance is the production of vitamin D by the irradiation of ergosterol. The development of the use of carbon tetrachloride against hookworm disease, and the prophylaxis of syphilis by the oral administration of stovarsol, are two other advances of great practical importance. The use of colloidal lead in cancer must also be mentioned, although it is difficult at present to make any certain estimate of the practical value of this method of treatment. Finally, the rapid development of knowledge concerning the ovarian hormones promises in the future to provide results of great clinical importance. These examples of recent progress in therapeutics indicate

¹ The Extra Pharmacopoeia of Martindale and Westcott. Revised by W. Harrison Martindale, Ph.D., F.R.C.S., Vol. I. Nineteenth edition. London: H. K. Lewis and Co. Ltd. 1928. (Fcap 8vo pp. xxxvi + 1207 2s. 6d. net.)

the large amount of new information that is contained in the latest edition of the *Extra Pharmacopoeia*.

At the conclusion of his preface Dr Martindale pays a tribute to the services to British science and industry of the late Sir Dawson Williams and the late Mr S W Woolley, who was formerly editor of the *Chemist and Druggist*. We are sure that we are voicing the general opinion when we say that the medical profession owes a great debt to Dr Martindale for his long-continued labour in providing it with an accurate and convenient summary of up to date knowledge regarding the innumerable drugs and preparations that are to-day offered to the physician for his use.

THE MEDICAL LIFE

It would seem to be a bold thing, if we may judge from the conventional criticism of the hour, to plan to day a series of handbooks for the guidance of ambitious youth. The younger generation, we are told in many paragraphs, has no use for the counsels of its seniors, and the good old days of respectful obedience are but a memory and a regret. Whether this melancholy strain is either as new or as true as its authors affirm it to be, may be questioned. In any event, nothing daunted, an enterprising publisher has acted on the conviction that *young men faced with the choice of a career may still welcome information and counsel from those who have walked the ways before them*. Hence the appearance of twelve "Vocational" guide-books dealing with all the professions, and each written by an authority of the first rank and order. In the series it is not without significance that while theology, law, medicine, education, banking, and journalism claim each a single volume, engineering engages three volumes—one each for its mechanical, electrical, and civil departments. Here, however, we are concerned only with *The Young Man and Medicine*,² written by Professor LEWELLYN F BARKER of the Johns Hopkins University, and we may say at once that anyone who is contemplating a medical career will find in these pages a faithful account of the difficulties and delights of the journey. Where there are lions in the path they are not concealed and the pleasant pastures are not presented in terms unduly expansive. The tale, in short, is a plain and unvarnished one but it is full of encouragement for those who are stout of heart.

As most of our readers have passed the threshold of decision and have acquired for themselves more or less personal experience of what life and work in medicine mean, Dr Barker has not perhaps much that is new to say to them. Yet his book is a very interesting one, and he has quite an individual word for such topics as the apprenticeship system, education before and after graduation, specialism in medicine, and medical societies, not to speak of less technical advice on fees, holidays, hobbies, investments, and matrimony, and even our respected seniors may collect a word of warning in the sentence, "One of the early signs of intellectual stagnation in a physician is the yielding to a tendency to neglect attendance upon medical meetings."

The chapter on the status, values and opportunities of the general practitioner has a decidedly refreshing quality, and Dr Barker has no ear for those who tell us that the function of medicine, in this application of it, is merely to direct the patient to the appropriate "specialist." After some recent announcements it is satisfactory to read on the authority of one who has had large opportunities for judgement, that "no other kind of practitioner, and not even a 'group' of specialists, can adequately perform the functions of the able general practitioner", and again, "the legitimate province of the general practitioner's work is much larger than the general public realizes." These conclusions seem to us to be based upon a wise appreciation of the position which the art of medicine must hold in the body politic. In a similarly robust and common-sense fashion Dr Barker deals with the subject of post-graduation study, and those who believe that such education and training are to be found only in the mysteries of a compulsory curriculum and under the shadow

of a special diploma, may profitably consider his conclusion that nothing in this direction is so important, for really keen students, as "the work that can be done by their own brains, with their own books, and on their own patients." The suggestion is that there may be so much running to and fro that opportunities that are at hand are overlooked and neglected. For many, such must be the only opportunities, and it is well to remember that within them lies much promise for those who cultivate observation and vision.

In a brief statement Dr Barker's book may be presented as a description in balanced and lucid terms of the material, mental, and moral values of a life spent in the study and practice of medicine—the discipline and rewards offered to the disciple, the service and succour contributed to the community.

THE SCIENTIFIC DESIGN OF ORTHOPAEDIC APPLIANCES

Dr GABRIEL BIDOU of Paris is known as an exponent of scientific principles in the devising and making of orthopaedic appliances,³ and two of his former works have been noticed in our pages. Orthopaedic instrument makers do not usually envisage their problems with the help of mathematical and dynamical formulae, contenting themselves rather with the use of broad principles only. Professor Babinski has already testified to the value of the work done by Dr Bidou for his patients at La Pitié. He seems to have been equally successful in the application of his method at the Salpêtrière Hospital, in which he was invited by Professor Georges Guillaumin to help in relieving the disabilities of paralysed patients. His success has been such that the Director of the Assistance Publique is about to arrange a special service of functional recuperation, to be in Dr Bidou's charge. In 1926 a foreign philanthropist, Dr I M de Hoz, founded the special hospital of Sainte Isabelle for the treatment of paralytic and helpless patients by Dr Bidou's method and under his direction.

Dr Bidou has substituted for the traditional and rule-of-thumb methods of his predecessors a method relying entirely on exact measurement. In the first place he measures the resistance, such as the weight of the paralysed limb, to be overcome, next the force required to effect certain movements of a limb or segment of a limb and calculates the strength and form of the various parts of the instrument required. For these purposes he has invented or adapted various instruments for measurement and certain improvements in the joints and other parts of appliances, which afford a nearer approach to the movements of living parts than his hitherto been thought practicable. After discussing the general principles involved, he proceeds to describe certain apparatus for the upper and lower limbs. These descriptions, which involve the use of a number of technical mechanical terms, are not easy for the reader unversed in engineering language to follow, and the rather elaborate illustrations of apparatus would be more intelligible if they had been reproduced upon a larger scale. It is not easy to ascertain whether in practice Dr Bidou has succeeded better than his predecessors in applying exact measurements to the solution of these problems, when it is so often difficult, or even impossible, to establish exact anatomical data from which to work. The proof of the pudding is in the eating, and a comparison of the functional results obtained at the Sainte Isabelle Hospital with those of older methods would be most valuable. Dr Bidou is certainly to be commended for his attempts to put the design and application of orthopaedic appliances on a really scientific basis.

SYPHILIS AND CANCER

It is generally admitted that certain syphilitic lesions—for example, tertiary manifestations in the tongue—may be succeeded by inorganic new growth, but Drs JACQUEMART and PRÉFÈRE in *Trépônème et Néoplasmes*⁴ go much

² *The Young Man and Medicine*. By Lewellyn F Barker M.D. LL.D. Vocational Series. New York: The Macmillan Company. London: Macmillan and Co. Ltd. 1928. (Cr. 8vo pp. xiv + 202. 10s. 6d. net.)

³ *Principes Scientifiques de Récupération Fonctionnelle des Paralysés*. Par Dr Gabriel Bidou. Préface du Professeur Georges Guillaumin. Paris: Le Livre Pour Tous. 1928. (6 x 7 1/2 pp. 151 figures. 20 fr.)
⁴ *Trépônème et Néoplasmes*. Par les Drs Jacquemart et Ch. Pfeiffer. Paris: N. Maloine. 1928. (6 1/2 x 9 1/2 pp. 168. 16 fr.)

further. According to them, all human tumours, simple as well as malignant, are due to the syphilitic virus. Cancers are quaternary manifestations of syphilis. Early syphilis, which is caused by the ordinary *Treponema pallidum*—a visible, non-spore-forming organism, sensitive to certain trypsinolysis—*is not* productive of cancer, but the older the syphilis becomes the more it develops the power of generating cancer. The old syphilis and congenital syphilis are due to invisible sporulating treponemata (an infra-virus or an ultra-microscopic virus) which are not affected by the various chemotherapeutic drugs. This invisible form infects the cells, and by provoking repeated karyokinetic brings about neoplastic formation. Syphilis explains cancer families, cancer houses, cancer districts, and cancer epidemics. Those races which have no syphilis or very little syphilis have very little or no cancer, and the campaign against cancer resolves itself into a fight against syphilis.

The authors have arrived at these interesting conclusions from a careful study of the cases of cancer that have come under their personal observation, but such a study, to be careful enough, entails a meticulous examination not only of each individual patient but of his ancestry, collaterals, and progeny. The results of the Wassermann test, supposing them to be negative, should not blind one, because it is well known that such a test is not always successful. One must be familiar with every sign and symptom that indicates a syphilitic taint. Here is a case at random: a woman has cancer of the breast, her daughter had a malformation of the vagina, which was treated surgically, and a child of this daughter was "un type d'hérédo." The proof of the thesis, thus, is quite easy. As the authors put it: "Il n'y a la aucun mystère, c'est d'une simplicité impressionnante, mais c'est évidemment trop simple pour être admis."

But it is not merely the clinical evidence that is relied on, more than half of the monograph consists of long quotations from various wise men (whose names are not infrequently misspelt) cunningly interpreted in support of the main or subsidiary contention. Several common sites of cancer are considered. The sceptic may ask, for example, what connexion exists between syphilis and such a common condition as cancer of the stomach. He receives this answer: Syphilitic lesions of the stomach have been found, and some of the finders have suggested that they are commoner than is generally supposed: a gastric cancer always succeeds a gastric ulcer, a gastric ulcer is caused by an obliterative arteritis which is due to syphilis, and the best treatment for gastric ulcer is bismuth, which, as everyone knows, is an excellent remedy for syphilis. It is admitted that all gastric ulcers do not become malignant, for the patient may die before this development occurs. The authors maintain that the circumscribed ulcers of the stomach and duodenum are always of syphilitic origin, but they are silent about the fate of duodenal ulcers, for duodenal cancers are pathological curiosities. Again, one might ask why syphilitic affections of the oesophagus scarcely exist outside textbooks, whilst carcinoma of the oesophagus is fairly common, and the answer is that the active functions of the oesophagus and its irritation by mechanical agents allow the treponemata to act so quickly that cancer results before a syphilitic lesion is appreciated.

The theory can explain many things that were obscure or uncertain. An instance is reported of a relatively large number of deaths from cancer in a part of a small town while the rest of the place was free. This was not mere coincidence. "Une jolie femme spécifique dans ce coin de village et tout s'explique le plus simplement du monde." Of course, syphilis does not affect the lower animals and yet they may develop cancer. But to each beast of the field there is its besetting parasite. The rabbit is subject to coccidiosis, but it is an invisible filterable form of the parasite that produces the cancer. Cancer may be produced in mice by applying coal tar to their skin. Tar is an exceedingly complex mixture, tar contains dyes, dyes are capable of staining nuclei, hence the tar damages the cell nucleus and allows a filterable micro-parasite to enter and cancer results. But with it all one detects a note of despair in the authors' remark: "Mais tout le monde n'est pas encore de notre avis."

NOTES ON BOOKS

THE textbook of gonorrhoea, edited by BUSCHKE and LANGER of Berlin in collaboration with twelve other Berlin professors and physicians, is a comprehensive treatise dealing with every aspect of the disease in men, women and children, with separate sections on the pathology and bacteriology, the affections of the male adnexa, eye, and skin, and on general gonorrhoeal infections, together with a full and practical account of modern methods of treatment both surgical and other. Chapters are appended on the related subjects of sterility and prostitution. The work is intended to embody the known facts relating to every branch of the subject and in every detail.

Man already owes a very considerable debt to the domestic fowl. While it is the case that few avian diseases are transmitted to man, bird malaria was the basis of the discovery of human malaria, and fowl cholera was the starting point of Pasteur's investigations, to mention only two of the outstanding examples. Dr. McGOWAN's book *On Rous, Leucotic, and Allied Tumours in the Fowl* draws attention to yet another. The study of malignant tumours is one which cannot fail to be of importance to human medicine, and Dr. McGowan raises many points of interest. He commences by discussing the nomenclature and origin of blood cells. He then records his observations on Rous No. 1 tumour, its intravital staining, and the spontaneous tumours of the Rous type which he has encountered as well as leucotic and melanotic tumours in fowls. Chapters on the role of the lymphocyte in avian pathology and on the etiology of tumours, are also given. Dr. McGowan's book is not a textbook, rather it is a statement of his own observations and views on a particular and very important group of tumours.

VOLUME XLII of the *Transactions of the Edinburgh Obstetrical Society* contains the papers read during the session 1926-27 many of these were reported in our columns at the time. In his presidential address which is included in this volume, Professor R. W. JOHNSTONE discusses the relations of gynaecology, medicine, and surgery from the historical and modern points of view.

PREPARATIONS AND APPLIANCES

AN IMPROVED STETHOSCOPE.

DR. J. KILPATRICK REID and Dr. W. OWEN MORRIS (Liverpool) write: We have felt for a considerable time that the existing types of stethoscopes are inefficient, or too cumbersome and expensive for general use. To remedy this we have contrived and have been using for some time an instrument which combines the handiness of the pocket phonendoscope with the clear transmission of the wooden stick stethoscope. The ear pieces are separate and made to twist well into the ears, where they remain firmly in place. The chest piece is of light composition and very durable, and causes no such pull on the ears

as does the usual heavy phonendoscope. The lumen of the transmitting tube is constant throughout and by tapering at the joints between the tube and the chest and ear pieces all dead space for backwash is eliminated. The chest piece is protected by a rubber cap to ensure comfort for the patient and added clearness to the transmission. The essential distinctiveness of the instrument is its exceptional conduction, together with a handiness for carrying about which we have found in no other stethoscope. It has the additional advantage of selling at a moderate price. The stethoscope has been made for us by Messrs. R. Sumner and Company, Limited, of 40, Hanover Street, Liverpool.

British Medical Journal.

SATURDAY, JULY 28TH, 1928.

THE PRESIDENTIAL ADDRESS

IN the course of his admirable Presidential Address on Tuesday last at Cardiff—an address which we print elsewhere in this issue of the *Journal*—Sir Ewen Maclean spoke of the “veritable pageant of advancement in the science and art of surgery.” Using the same metaphor, we may say that the new President of the British Medical Association has presented to us no fewer than three pageants—that of ancient Cymric medicine, that of the work of the British Medical Association for the public, and that of progress and research in the field of medicine since the last Cardiff meeting of 1885. Able as showman and as chorus, in his presentation of the material and in his accompanying comments Sir Ewen Maclean worthily maintained the really high level of the whole series of Presidential Addresses. Both as a rapid and interesting historical survey and as a convenient and valuable assemblage of relevant facts, the Address will well repay perusal, even as it pleased its hearers. In that portion of it, indeed, which dealt with the earlier development of the Welsh *meddyg*, there was more than one indication that the President could reveal himself as a fascinating teller of folk tale or fairy story.

Sir Ewen Maclean is the first President of the British Medical Association who has also held office as Chairman of the Representative Body. It is perhaps, therefore, all the more natural and appropriate that he should have devoted considerable time and care to a public demonstration of the fact that the great power and influence of the Association is not, as is sometimes alleged, expended predominantly in the personal interest of its members, but that from its foundation ninety six years ago the Association “has been concerned chiefly with the maintenance of the professional standard of education and conduct, both pre and post graduate, the promotion of scientific research, and the development of a national public health policy which will allow the profession to make its maximum contribution to the well being of the community.” It has not yet been realized by many members of the Association itself, certainly not by the public at large, how preponderant has been the influence of the Association in bringing about those salient changes in legislation and administration which have had the most profound effect on the health of the community. To name but a few of these, it may be pointed out that it was the British Medical Association which first suggested, long ago, that a special department of Government should be created to deal specifically with matters of public health, which went on insisting on this proposal year after year, and which was the actual force that, in the fullness of time,

brought about the establishment of the Ministry of Health. It was, too, an investigation and report and recommendation of the Association which was largely responsible for the creation of the School Medical Service. Action in regard to ophthalmia of the newborn is almost entirely due to the Association's influence and instigation, and the same may be said of community care for the mentally deficient and epileptic. Though the same cannot be maintained with regard to national health insurance, it is yet true that it is the Association's work and influence more than that of any other single body (always remembering the individual labour, enthusiasm, and skill of Sir Robert Morant) which has transformed a creaking, lumbering, imperfect machine into a useful and beneficent instrument of public good.

Even at the Cardiff meeting of the Representative Body (of which the first part of our full report appears in this week's *Supplement*) there were discussed four considered pronouncements, with recommendations of the Council, on important matters of public interest: the regulation of treatment by means of electricity and radiation, puerperal morbidity and mortality, lunacy law reform, the co-ordination of hospitals. It is probable that, as in similar matters heretofore, all these will ultimately come to fruition on the general lines of the Association's policy. Public work of this kind goes on week by week, but very little public recognition is accorded to it. It is well that the President should have invoked a wider attention. He might even have gone further, and pointed out that each year the Association awards one thousand pounds in scholarships and research grants, and devotes a considerable further sum of money to educational lectures, to special medical and health inquiries, and to collective investigations into the origin and treatment of diseases.

Of the pageant of medical progress and research since the Cardiff meeting forty three years ago Sir Ewen Maclean said: “The achievements are stupendous, and represent a vast saving of human suffering and an appreciable prolongation of human life. These results are not the product of knowledge acquired casually or in haphazard fashion, but the basis of real advance has been framed, as it always will be, in tireless, persistent, relentless toil.” Much of the wide field of bacteriology, and almost the whole of biochemistry and endocrinology, has been developed since then. Tuberculosis, as Sir Robert Philip told us a year ago in his Presidential Address at Edinburgh, is on the way to being conquered, diabetes and pernicious anaemia have lost much of their terror, and at least a beginning has been made towards getting a grip on the scourges of rheumatism and cancer. Moreover, it is not true to say, as is sometimes said, that there has been no improvement in maternal mortality. The fall in the puerperal sepsis and mortality rate has been appreciable, but it has not been proportionate to that of the general or of the infant death rate. Thus, like those of rheumatism and of cancer, is a baffling problem. It is not susceptible of any easy or simple solution, either scientific, medical, or administrative. It is fitting that Sir Ewen Maclean—as, we believe, the first gynaecologist and obstetrician who has occupied the Presidential chair,

and himself one who, by his own distinguished work, is entitled to speak with authority—should give some prominence to this matter. His words will be seriously weighed, and we hope that the findings and recommendations of the special committee of the Council of which he has been the chairman will be appreciated by the public and taken advantage of by the Departmental Committee which has recently been appointed by the Ministry of Health. In this sphere, too, the pioneer, though necessarily inconclusive, work of the British Medical Association should be acknowledged.

It is desirable that particular notice should be taken of the concluding and novel suggestion of the President with regard to the position of the British Medical Association in relation to post-graduate teaching. It is known that the Council and Representative Body—and, indeed, the general body of members for whom they speak and act—have for some years taken a great interest in this subject. It is of vital importance to them and to the public, and of even more than usual interest to that large body of membership of the Association coming from overseas. Much useful thought has been given to the matter, but very little has yet been done. Sir Ewen Maclean says: "I have long felt that, with its wonderfully ramified machinery to link up the provinces and the capital, the rural areas and the towns, no body is so well adapted as our Association to organize a post graduate system embracing existing institutions and developing many new centres on a scale worthy of this country. I am not without hope that there may be forthcoming a national benefactor willing to entrust the Association, as a voluntary body with the considerable sum of money necessary to establish and conduct such a system. The machinery is appropriate. The need is great. Where is the benefactor?"

There is an obsolete phrase, to play one's pageant—as we should now say to act one's part. It is apropos, perhaps, to conclude by saying an legendary luster tells us Launcelot said unto Arthur,

How now, yonder rideth a knight that playeth his pageants

THE INTERNATIONAL CANCER CONFERENCE

WE conclude in this issue our report of the International Cancer Conference which was held in London last week under the presidency of Sir John Bland Sutton. It is difficult to give a full appreciation of the proceedings so wide and varied were the subjects under discussion, but at least it is certain that favoured by unusually brilliant weather the Conference achieved an equally brilliant success which probably surpassed the expectations of those responsible for it. All the arrangements proceeded with the utmost smoothness, which spoke of a highly efficient organization and much expert, detailed, and willing work by the committees and secretarial staff. The whole medical profession owes a debt of gratitude to the British Empire Cancer Campaign for the promotion of this undertaking, which has brought credit to itself and to the profession in this country. The success of the social aspect of the Conference was assured at the outset by the reception of the overseas delegates by His Majesty the King on Monday, July 16th—a simple and yet dignified ceremony, which was highly appreciated by them. A remarkable gathering of men and women, whose names are known throughout the world

in cancer work, was seen that evening at the reception by Sir John Bland Sutton, and the reception by the Duke of York at Lancaster House on Wednesday provided a brilliant spectacle in a delightful setting, which could not have been better chosen for an occasion of the kind.

The work of the Conference was opened on Tuesday by a letter from the Duke of York, as President of the Campaign, followed by an address of welcome to the delegates by Sir John Bland Sutton. Two general discussions were then initiated—on 'The relative values of surgery and radiation in the treatment of cancer of the cervix uteri and the rectum, and on 'The etiology of cancer. In the former the opinion gradually crystallized that treatment by radium in massive doses over long periods, either with or without surgical access to a tumour, must be regarded, except in very early cases, as having a value at least equal to that of pure surgical methods. The discussion on etiology, opened by Professor Ewing on a broad basis, was carried on by a distinguished series of speakers, and here one of the most important communications of the whole Conference was made by Dr James B. Murphy of the Rockefeller Institute. At his hands the virus theory of cancer, eloquently supported at this meeting by Professor Borrel, again received a severe blow. Murphy, working with the Rous chicken sarcoma, had found that these tumours were highly specific for the fowl, and that the unknown filterable agent reproduced the peculiar character of each individual tumour. These were facts telling against the parasitic nature of the disease. Experiments also showed that the chicken tumour agent was more resistant to the ultraviolet light energy than either bacteria or the viruses, and that it entered into a direct combination with the muscle tissues of susceptible fowls. A very notable advance is the isolation and the purification of the active agent by fractional precipitation of the proteins from extracts of the chicken tumour. It appears that this purified fraction is chiefly of nucleo protein nature and is capable of producing tumours in fowls with great regularity. This repeated fractional precipitation is itself strong evidence against a living virus as the active agent but the crowning proof which dramatically was reserved to the end, was the isolation of this active fraction capable of producing tumours, from the testicles of normal fowls free from contact with tumour-bearing animals. Analogous, though independent work on the Rous tumour, tending to confirm the enzymic character of the agent was reported by Professor Leitch. Whether this work on the fowl sarcoma can be brought into relation with the cause of mammalian tumours or whether it will remain *sui generis*, future investigation alone can show.

The difficult subject of The classification and treatment of bone sarcoma, opened on Wednesday by Professor Ewing produced an interesting and valuable discussion in which emphasis was laid less upon amputation than upon the combined method of radium and bone surgery advocated by Mr. Handley. For certain cases Dr. Coley's fluid received commendation. Primary carcinoma of the lung received able treatment at the hands of Dr. Hutchison, Dr. Burrell and Professor Shennan. The increased frequency of this condition appears to be undoubted, though its cause remains obscure. The interesting fact emerged from the discussion on the Biological effects of radium and x rays that, although working with different methods, practical agreement on the wavelengths to be employed has been reached by different

observers "Occupational cancer" produced a balanced and careful statement of this condition, the importance of which is receiving increasing recognition in other countries. The fact of individual susceptibility was emphasized by several speakers, a point to which sufficient attention has not always been paid. The exciting cause and the natural history of the disease in this field of cancer work being comparatively definite, there was a considerable measure of agreement as to methods of treatment and the possible lines of prevention. A valuable contribution to this discussion was the work of Professors Schmorl and Rostoski on the Schneeberg lung cancer.

The discussion on the relative values of surgery and radiation was continued on Thursday morning, with special reference to cancer of the buccal cavity and the breast. Here again the value of radium, especially in the treatment of cancer of the buccal cavity, was convincingly shown. The demonstrations at St. Bartholomew's Hospital afforded excellent evidence of the use now being made of radium in the treatment of growths at various sites, and the display of tissue cultures from the Strangeways laboratory at Cambridge, taken in conjunction with Dr. Cantu's remarkable cinematograph film of cells dividing or exposed to radium, indicated the modern developments of cytological study in relation to cancer. The demonstrations at the Middlesex Hospital and the Radium Institute were also full of interest and were well attended. The discussion on the chemotherapy of cancer, with particular reference to lead, shed a little warmth, but not much light, on this keenly debated question. The evidence seemed to show, on the one hand, that some cases had improved during, and possibly as the result of, lead treatment, and on the other that lead is a dangerous drug, unfitted for general use owing to the narrow margin of safety, opinion as to its value still remains unsettled. The serological work of Dr. Lumsden, and the chemical compounds described by some other speakers, indicated alternative methods of treatment other than by lead. Admirable demonstrations illustrating the various phases of the work of the Cancer Hospital and its Research Institute were to be seen on Thursday afternoon. The Lister Institute, St. Mark's Hospital, and the Westminster Hospital all gave interesting exhibits, which were well attended. Sectional discussions on Friday morning illustrated the difficulty of early diagnosis of cancer of the stomach, the importance of earlier treatment of chronic gastric ulcers, and the necessity for laparotomy in doubtful cases. In another section the importance of using all methods in the diagnosis of cancer—microscopic, radiological, and serological—was made manifest, in spite of the limitations of each of them. In the important sections dealing with public health racial differences were noted but not explained, and it was also shown that public education has in fact led to earlier treatment of the disease. The technical work of the Conference ended with visits to the Medical Research Laboratory at Mill Hill, to Guy's Hospital, and to the Royal College of Surgeons, where special demonstrations were given on specimens of scientific and historic interest.

Such, in brief outline, was the work of this Conference, which has not only stimulated great public interest, but has focused scientific attention from all countries upon many phases of the cancer problem. It has done much to foster good international relations, and the many foreign and Dominion delegates will carry away with them pleasant memories of our country. The scientific results may well be such as to form a landmark in the history of cancer research.

ANNUAL MEETING NOTES.

"The Book of Cardiff"

A HANDSOME volume, lavishly illustrated, has been produced by the Printing and Publishing Committee at Cardiff, and a copy has been given to every member attending the Annual Meeting this week. *The Book of Cardiff* differs in shape and size from the corresponding volumes of previous years, though its arrangement and scope are not unlike those of some of its predecessors. The purpose of the committee has not been to provide a formal guide-book, but rather to introduce readers to the history and present-day activities of Cardiff, and indicate the important part played by it in the life of the country. The keynote of the book is struck by Dr. D. R. Paterson in the opening words of his introduction:

"Cardiff suffers in the mind of strangers from two misconceptions. They generally seem to think, first that it is an entirely modern and even mushroom town, and secondly, that it is black with coal dust and coal smoke. As a matter of fact Cardiff is among the oldest towns in the country, and, at all events for a business town, among the cleanest."

Many readers will recall the descriptive and historical notes on Cardiff and its neighbourhood contributed by Dr. Paterson to our columns in recent months, and this volume will go far to satisfy their wish for further information about a subject full of interest. The longer sections include a concise account of Cardiff Castle by Mr. John P. Grant, and a description by Mr. W. S. Pugh of the fine public buildings of the city, which have been the admiration of every visitor during the past few days. It is not too much to say that in Cathays Park will be found some of the best modern architecture of its kind in our country, the buildings admirably grouped in relation one to the other, and placed in a setting of which every advantage has been taken. An outline of the history and present position of the University College of South Wales and Monmouthshire is contributed by the Registrar, Mr. D. J. A. Brown, and an account of Llandaff Cathedral by Mr. John Ballinger. The great position held to-day by Cardiff as a seaport is revealed in the sections dealing with the Bute Docks and with Cardiff as a centre of distribution, and Mr. D. Willson Lloyd brings out the intimate relation between the Port of Cardiff and the South Wales coal field. As becomes a book mainly addressed to medical readers, considerable prominence is given to matters relating to medicine. Thus Professor A. W. Sleen contributes an article on the Welsh National School of Medicine, Professor D. A. Powell outlines the work of the King Edward VII National Memorial Association, Dr. Ralph Picken (M.O.H. for the city) supplies a note on the health of Cardiff, and the kindred subjects of municipal water supply, parks and recreations, and town planning are likewise brought to notice. The illustrations, as we have implied, form a striking feature of *The Book of Cardiff*, and for this reason if for no other it will be valued as a souvenir by those members of the British Medical Association who have had the good fortune to take part in the ninety-sixth Annual Meeting.

The Representative Meeting

Friday, July 20th

We publish in the *Supplement* this week our full report of the first two days' proceedings in the Annual Representative Meeting at Cardiff. The first morning session was, as usual, largely occupied with matters of domestic interest. For senior members the opening proceedings were marked by a sense of loss and change—loss, intimate and personal, expressed in Dr. Brackenbury's tribute to the memory of J. A. Macdonald and Dawson Williams, change in the unfamiliar aspect of a platform lacking the accustomed presence of Sir Robert Bolam, and looking for legal

support to Mr Oswald Hempson in the place of his father. The nomination of Mr Hogarth and Sir Robert Bolam as Vice-Presidents of the Association, and of Mr A H Burgess of Manchester as President for 1929, and Dr W Harvey Smith of Winnipeg for 1930, was received with acclamation. The representatives showed little hesitation in casting off the cumbersome machinery of the single transferable vote and returning to the method of the simple majority vote as that most appropriate to elections in a relatively small constituency on an individual and personal basis rather than one of party or policy. The proposal by Sunderland that the Representative Meeting should be dissociated from the scientific and social activities of the Annual Meeting by locating the former permanently in London received a decided negative. A suggestion by the proposer that this expedient had been put forward with a view to enhancing the attractions of the Annual Meeting for the general practitioner was not fully expounded. The Brighton motion directed to securing more adequate recognition of the services of members of the Association was dealt with by the only means available when a definite decision either way must do violence to a considerable body of sentiment. The rest of the morning, apart from the interlude of the Lord Mayor's warm welcome to Cardiff, his generous appreciation of the scope of the Association's deliberations, and the first appearance of the President-Elect on the platform, was devoted to a discussion of the Association's relations with the organized profession in other countries, on the motion of Dr Douglas and Dr Lyndon, which was taken as covering the Brighton motion on the same subject. The debate recalled the judicial dictum "I agree with my brother on the left, for the reasons given by my brother on the right." The ultimate decision, carried by an overwhelming majority, was that the Association should not lag behind the British Dental Association on the one hand, and the general public on the other, in its recognition of international obligations and opportunities. The confusion of mind engendered in the attempt to eliminate sentiment, even in considering a question of finance, was, as the Chairman of Council and Dr Cox both pointed out, demonstrated by the Council's original suggestion that membership of the A.P.I.M. would entail unjustifiable expense, but that the greater part of the work incidental to membership should be freely undertaken by the Medical Department on the request, not only of that, but of any other medical organization. The discussion afforded the meeting an opportunity to enjoy Dr Douglas's eloquent reasoning, and to acclaim the Medical Secretary in the character of an unashamed sentimentalist.

During the afternoon session the meeting dispatched the Finance, Building, Organization, Journal, and Science reports, and began discussion of the motions submitted in the Ethical report. Under Finance, Dr Martley's gallant attempt at criticism called forth some attractive essays in definition on either side, and allowed the Treasurer to supplement his lucid opening statement by an explanation of points he had in the first instance passed over as obvious. The motion from South-Eastern Ireland for a compulsory scheme of life insurance, proposed formally from the chair, did not command support, even in the modified form suggested for educative purposes by Dr Walker and Mr D D Evans. The motion from Bath for a reduction of the annual subscription to two guineas, put forward by Dr Gordon in a manner which indicated clearly enough his own opinion of its merits, elicited a reply from the Treasurer, in which he assessed the value of the Association to a member at thrice the amount of his subscription. Sir Robert Bolam's report on the work of the Building Committee raised no criticism and little inquiry—perhaps because of his frank admission that the Committee had as yet produced no buildings. The presentation of the report on Organization by Dr Morton Mackenzie was

distinguished by the remarkably short time occupied in dealing with over four pages of the agenda paper, and the number of "schools of thought" detected by Dr Fothergill amongst the representatives. Such discussion as took place was almost wholly directed to an unsuccessful attempt to improve upon the wording of the by-law recommended in substitution for that which has regulated the subscriptions of members engaged exclusively in the work of medical instruction or medical research. Beyond this it enabled the Chairman of the Representative Body to live up to his renown for scrupulous accuracy of interpretation by demonstrating to the meeting that the accepted practice in respect of amendments placed on the paper by Divisions and Branches was indubitably out of order under the existing by-laws. He subsequently modified the rigour of his ruling by promising to provide personally a means of escape from its application for the remainder of the meeting. The report on the progress of the *Journal* during the past year required no discussion or explanation, but it gave Sir Robert Bolam the opportunity to introduce to the representatives Sir Dawson Williams's successor in the service of the profession through the *British Medical Journal*—an introduction warmly welcomed by the meeting. The report of the Science Committee again provoked comparatively little controversy. The verbal amendment proposed by Hendon on the motion dealing with remuneration of non-professorial medical teachers and laboratory and research workers was readily accepted by Mr Sontar. The main recommendation—that on treatment by radiation and electricity—was debated in some detail, but unfortunately the discussion was less calculated to inform the public on matters very urgently requiring attention in the interests of the health of the community than to confuse them as to the medical practitioner's general attitude in accepting responsibility for such treatment as he may prescribe for his patient. The general acceptance by the representatives of the principle underlying the motions of Aberdeen and Lancashire and Cheshire in connexion with an investigation of the composition of secret remedies by the Association may have done something to mitigate the impression created by the previous debate. The time at disposal between the approval of the Science Committee's report and the adjournment at 6.30 p.m. barely sufficed for the development of the strong feeling which is inevitably engendered by an open discussion of the more delicate and complex problems of ethical procedure.

Saturday, July 21st

Taken as a whole, the second day's session was remarkable for the sustained interest of the discussions, the relative absence of desultory and irrelevant comment, and the amount of highly controversial ground covered. The difficulty of the position which gave rise to the motion by North Middlesex for rendering ineligible for membership a non-member who has accepted and continues to hold a post on terms contrary to the declared policy of the Association was clearly defined in the course of discussion on that motion and of the amendment submitted by Hampstead. The decision to remit the matter to the Council was the outcome of a strong sense of the injustice of the position which has, in fact, been reached in certain cases in existing conditions, balanced by a healthy appreciation of the dangers implicit in the remedies actually proposed. Dr Dain's report on the position created by the provisions of the new Health Insurance Act in connexion with additional medical treatment benefits, reinforced by Dr Brackenbury's lucid exposition, met with a ready response from the Representative Body as a whole. The representatives showed themselves more anxious to understand the position and lend the full weight of their support to those immediately responsible for safeguarding the position of the profession under any new schemes, than to

enjoy then very obvious opportunities for criticism. The debate should have gone far to assure Dr Brackenbury that before the representatives passed to the next section of the agenda "almost all of them" actually understood the points at issue and the methods necessary to guard against all the possible dangers. The motion by Windsor on the periodical medical and dental examination of insured persons owed its success largely to the manner in which it was handled by Dr Casson. The danger that an excellent piece of health propaganda might have its effect spoilt by inopportune emphasis upon the economic implications for the profession was an obvious one, and later in the day might well have proved insuperable. It was with the introduction of the medico-political report that the temper of the meeting changed. On the proposals for general approval, as a basis of negotiation, of the Council's recommendations for the conditions of service of assistant medical officers in mental hospitals, the York amendment (argued by Dr Peter Macdonald with his accustomed vigour and restraint) served, together with the Perth amendment, only to emphasize the care and foresight with which the Council's proposals had been drawn up, for on every point raised direct issue was joined by Dr Brackenbury or Dr Bone, and the sense of the meeting was sufficiently clear to justify the withdrawal of the major amendments. From the start of the discussion on paying centres for infant hygiene, the presence of the Chairman in appealing at this point for "a maximum of forbearance and a minimum of conversation" became apparent. The meeting, as a whole was determined to stand fast on the ground that private practice must be defended from unwarrantable encroachments, and quite simply and very effectively declined to consider the Council's plea for a most carefully weighed and adjusted piece of health propaganda, or the plight of that section of the public which, to secure from the existing body of general practitioners the guidance it needs, is in all good faith appealing to the profession for help in creating a new source of supply. From the moment when Mr Turner brought his address to a term amidst enthusiastic applause it became clear that further argument was useless and that most of the representatives had made up their minds. The debate was, however, responsible for a contribution of unusually high quality from Dr L. W. Batten, and a sane and balanced appeal to past experience from Dr Christine Murrell. Inspired by this victory, the Representative Body had itself just enough in hand to refuse the representative of Darlington permission to withdraw a vote of censure on the Council for the formulation and publication of its recommendations on the contract rates for juvenile Oddfellows without first seeking the permission of the Divisions. This slight difficulty disposed of, a close conflict was joined between Dr Bone and the several "schools of thought" to be distinguished amongst the representatives. It was Dr Bone's strength that he based his argument on facts gathered from the whole country and an evocation of general experience of the profession. The weakness of his position was that no individual (or school of thought) seemed prepared to check the validity of a particular experience by comparison with general experience. The chief defect of a discussion maintained at a really high general level appeared to be a tendency to stand too much on the shifting ground of professional dignity. Eventually, after the introduction of the three minutes limit to speeches, the debate ended by rejection of the motion to refer back, and acceptance of the Council's proposals by 81 to 63—a margin insufficient to give to this verdict the status of a decision of the Association. It remains for the Divisions to find some other means either of altering the facts quoted by Dr Bone, or of assimilating them before the subject comes before the Representative Body again.

The Welsh National Memorial

Before the representatives left Cardiff on their Sunday excursion they assembled around the Welsh National War Memorial in Cathays Park, when a wreath was deposited in the name of the Association at the foot of the memorial. Owing to the fact that Sir Robert Philip, the President of the Association, had not then reached Cardiff, the ceremony was performed by Sir Llew Maclean, the President-Elect, with whom were the Chairman of Council and the Chairman of the Representative Body. The wreath, a large and beautiful one, in which red roses predominated, was deposited by Sir Llew Maclean, who said that it was his privilege to do so in the name of the British Medical Association in remembrance of the sons and daughters of Wales who gave their lives for King and country in the great war.

Luncheon to Overseas Representatives

The officers of the Association and the Chairmen of the Organization and Dominion Committees entertained at lunch on the first day of the Representative Meeting the representatives attending from overseas Branches of the Association. The number of these guests present was sixteen, and in addition there were nine members of Council representing the profession in the Dominions and Colonies. Dr C. O. Hawthorne, who presided, said that this was not meant to be a formal and official ceremony, but rather an opportunity for the promotion of good fellowship. He welcomed the guests as representatives of Branches in which the whole Association felt, naturally, a special interest, and he took occasion also to express the appreciation of the Association at home for the way in which generous and overflowing hospitality had been extended to those who in their turn had gone across the seven seas from the centre of the Association to its periphery. He assured the overseas representatives that the Central Council had a very ready ear for any suggestions which would make the Association a more successful professional organization and a more effective instrument of public service throughout the Empire. Mr C. L. Leopoldt (South Africa) was called upon to respond as one who "carried the British Medical Association with him in parenthesis"—an allusion to the title of the South African organization. Mr Leopoldt said that the parenthesis was like the dog's tail, which wagged the dog, he hoped that the Association would continue its "wagging." In South Africa they were accustomed to look to the central body of the Association for inspiration and stimulus. To their great delight they had had visits from the Medical Secretary and later from Dr Brackenbury, and the visits had been the means of knitting the Association in South Africa more closely to the Association in the Mother Country. Professor D. B. Blacklock (Sierra Leone) also briefly responded, associating himself with what Mr Leopoldt had said about the indebtedness of the profession in those far-away places to the profession at home. Some further remarks were made by Dr G. W. Hart (New Zealand), who pleaded that consideration might be given to the facilities for post-graduate work in this country for those who came from the Dominions. One of his colleagues in New Zealand, who had visited both America and England, spoke regretfully of the absence of post-graduate opportunities in England as compared with their almost embarrassing profusion in the States. In America, instead of having to go and inspect lists, advance programmes were posted on to him, and a car was even sent for him at six in the morning to take him to see an operation. Many of the younger graduates in the Dominions would like to come over to see refinements in surgery, they did not necessarily want elementary teaching. Dr C. B. Blackburn (New South Wales) spoke to the same effect. In America there was no difficulty at all in finding post-graduate facilities,

it was a matter of picking and choosing. Dr Hawthorne said that the ambition expressed was one which enlisted everyone's sympathy. The difficulty of carrying out an organization for post-graduate teaching was considerable, but undoubtedly a movement in that direction was desired, and they all hoped that in course of time it would come to full fruition. In addition to those mentioned, the following overseas representatives were present at the luncheon party: Dr L. R. Grey and Dr J. O. Twomey (Border Branch, South Africa), Dr A. W. Sanders (Pretoria), Mr E. H. Hunt (Hyderabad), Dr G. D. R. Black (Hong-Kong and China), Dr R. G. McPhee (Victorian), Dr R. D. Fitzgerald (Singapore), Dr H. V. A. Gatchell (Tanganyika, Mashonaland), Dr Gordon Spencer (Mesopotamia), Dr A. G. H. Smart (Penang), Dr A. Murphy (Queensland), and Dr Fergusson Stewart (Western Australia). The representatives of overseas Branches on the Council present were: Dr F. J. Gomez (British West Indies), Lieut-Colonel Ashton Street, I.M.S. (India), Dr O. Marriott (Hong-Kong), Mr T. P. Dunhill (New South Wales and Queensland), Dr G. Clark Trotter (New Zealand), Sir Jenner Verrall (South Australian, etc.), Dr Barcroft Anderson (South Africa), Sir Malcolm Watson (Hong-Kong), and Dr W. Watkins-Pitchford (South Africa).

The Religious Service

The official religious service was held in the Parish Church of St John Baptist, Cardiff, on Tuesday afternoon. The preacher was the Rev Garfield Williams, O.B.E., M.B., B.S., Honorary Canon of St Albans, and the Bishop of Llandaff was present. Members assembled and robed in the City Hall, from which a procession was formed to the church, preceded by the Cardiff banner which ordinarily rests, with the other emblems of cities of former Annual Meetings, in the Great Hall at Tavistock Square. The Lord Mayor and certain officials of the Corporation, preceded by mace-bearers, went in advance of the Association procession. At the service Charles Kingsley's hymn, "From Thee all skill and science flow," was sung, and the lesson (Isaiah lv) was read by the President of the Association, Sir Ewon Maclean. Canon Garfield Williams's sermon was an exposition of the character of St Luke, the "beloved physician." He emphasized the evangelist's professional attributes, including his insatiable curiosity about the personal details of those with whom he came in contact. "The general public imagine that in our profession we treat diseases, but we do not, we treat persons. You cannot treat disease *in vacuo*, any more than you can deal with anything else in that way which has to do with personality. Perhaps medicine may have something to teach educationists in this respect. The teacher too often imagines that he can teach a subject, a science, or even a creed, but he can only teach a person." Another trait of St Luke to which the preacher drew attention was his eminently practical mind. He was a companion of Paul the visionary, but it was Luke, the travelling physician of the Levant, who thought out the ways and means. What must this new religion have meant to St Luke as he journeyed from place to place in the Eastern Mediterranean? He must have witnessed how it brought about an inward peace in a distracted world. Peace—a word curiously abused—might be acquired through callous cynicism or through self-satisfaction, but the peace which Luke observed in his fellow religionists and experienced in his own heart was very different and infinitely more sure. It was something which brought serenity and courage and hope in a world where, then as always, noise and glare had largely displaced music and light. Another lesson to be drawn from St Luke, and one which was needed by the present age as much as any, was his conception of the Kingdom of God as a biological growth, not as

a crystalline accretion. The things that mattered in religion were not the filling or the emptying of churches, the saying or not saying of creeds, the acceptance or rejection of revisions, but the inward life, the growth from within outward, expressing itself in modest and beautiful character such as Luke's, and self-denying service such as he rendered to his Lord and his brethren.

LORD BALFOUR ON SCIENCE AND PHILOSOPHY

THE EARL OF BALFOUR, as president of that body, on July 16th gave an address to the third annual meeting of the British Institute of Philosophical Studies—which exists to establish contact between the professed philosophers and the educated public—dealing mainly with the philosophical problems arising from the advance of physical science. His words deserve consideration from all who, like members of the medical profession, are daily involved in the difficult task of reconciling the apparent, as suggested by perception, with the real, as partially disclosed by an incomplete science. It is perhaps appropriate at this juncture to remark on the peculiar fitness of Lord Balfour for the part of mediator between the point of view of the world at large and that of the laboratory and the study. Lord Balfour—who has attained his eightieth birthday since the address was delivered—as Lord President of the Privy Council, is the titular head of the Department of Scientific and Industrial Research and of the Medical Research Council, and the Minister to whom the General Medical Council is responsible. His first philosophic work was written some fifty years ago, and his experience as a Minister of the Crown goes back almost forty years. In view of these circumstances, and of the known clarity of his mind, his address is of unusual interest, he took as his text some words of Professor L. T. Hobhouse: "Philosophy does not consist in pieces of knowledge, but primarily in an attitude, a desire to understand and appreciate." Lord Balfour agreed with this statement, and proceeded to discuss two of the problems which one should understand and appreciate—the problems of perception and induction. The plain man would ask what there was specially requiring to be understood in such simple matters. Perception and induction were fine names for the simple operations of observing the world in which we lived and drawing conclusions from our observations. Mankind was always doing it, mankind had always done it, and with the progress of natural science they would do it more successfully every year. So, said Lord Balfour, thought the plain man. But it was just science that was the cause of their troubles. In pre-scientific days formal logic, morals, metaphysics, and metaphysical theology chiefly occupied the thoughts of philosophers, to these had now been added problems raised by physics, and these all involved perception and induction. Taking, as the most important and most obvious kind of perception, perception by seeing, the speaker described the complex train of causes and effects underlying this process—the emission of energy by electrical charges from matter, the propagation of ethereal waves, followed or accompanied by the psycho-physical process which in each individual case converted the physical message into a mental perception. There was a monotonous simplicity, continued Lord Balfour, about the world he had attempted to describe, and it could not be pictured as possessing either beauty or variety. But it was not merely aesthetically unattractive, it had the further defect of possessing no resemblance to the world they saw. The more they knew what reality was, the less did natural fact harmonize with perceptual experience. In these circumstances, he asked, what became of experience, and by what process of logical legerdemain was science extracted from observation? They lived in a world of illusions, how, by observing such a world, did they succeed in reaching realities? This was one form of

the second question—namely, What is induction? The inductive logic which should justify the inference of general laws wholly from particular observation, even when the observations were admittedly valid, had, in his opinion, still to be discovered. What were they to think of such a task when the observations were admittedly invalid? What were they to say of the self-satisfied theorizing of the eighteenth and nineteenth centuries now that seeing had not only ceased to be believing, but was in open revolt against it? He would make no attempt to solve these difficulties, it sufficed if he had succeeded in giving some support to Professor Hobbouse's statement. Lord Balfour concluded: "I do not suggest that it is every man's duty to be a philosopher, or to spend his time speculating about the universe. I do suggest that those who make no effort to get beyond the teaching of common sense should do so in no boastful or self-confident spirit. Whenever they find common sense opposed to science, let them throw in then lot every time with science. To the man of science, on the other hand, I would say that science, though on the way to truth, is always incomplete and not always true, and that in the present state of our intellectual development its ultimate basis, deeper even than experiment and observation, is faith." Could there be, he asked, a better justification for the existence of such a society as theirs?

B C G

AN excellent summary of the work which has been done in France with B C G (*Bacillus Calmette Guérin*) during the last seven years is given by Dr G. Poix in *La Presse Médicale* (July 11th). After noting that observations in Belgium, Rumania, Greece, Italy, Holland, Norway, Russia, Spain, Austria, Germany, and the United States have confirmed Dr Calmette's work, Dr Poix briefly describes the experimental studies that have been made, and the statistical results, such as they are, of 94,301 vaccinations of the newly born in France. He then deals with certain reservations as regards the efficacy of the treatment made by Austrian authors in particular, and asserts that sensitiveness to tuberculin and immunity are two states, distinct and independent, in organisms infected by the bacillus of Koch. Consequently the fact that the cuti-reaction does not always become positive in the weeks following vaccination is no indication that the subject is non-immune. The duration of the protection given by vaccination remains doubtful, but the infants vaccinated by Weill Halle and Turpin between 1921 and 1924, living in tuberculous surroundings, appear still to maintain their resistance to the disease. The objections to vaccination of infants not exposed to infection, which were recently raised by Dr Lagnieres of Buenos Aires at a meeting of the Académie de Médecine, are shown to be of no validity, they met with no support from the Académie. Whether the subcutaneous administration of B C G to adults, as recently performed by Heimbeck and Schell in Norway, is justifiable remains to be seen. In any case the method can only be applied satisfactorily in specially organized centres for the treatment of tuberculosis. Dr Poix quotes Fontenelle as praising prolonged distrust as the acme of reason, but he considers that the facts about B C G which he has summarized no longer justify scepticism.

PHOTOCHEMISTRY

WE wonder how many of the numerous practitioners of the modern methods of actinotherapy ever reflect that their brilliant clinical results depend fundamentally on the science of photochemistry. Professor Plotnikow, in a short treatise on this subject,¹ has done his best to induce the clinician to contemplate the principles which underlie the art which he applies to the treatment of his patients.

The clinician will not, indeed, glean any tips to enable him to grapple more successfully with those few ailments which even the most whole-hearted of ultra-violet-ray enthusiasts still admit to be intractable to their magic, but he will learn the laws that govern the chemical action of light, the conditions which determine whether any particular compound is susceptible to its influence, and how to calculate the speed or intensity of the reactions invoked, in short, he will gain the advantage of being able to view his own subject from a new angle. As a matter of fact, the author does not claim that he is able to make any contribution to actinotherapeutics, he is more concerned to apply his science to the problems of physiology, especially plant physiology, in which the actions of chlorophyll and some other allied bodies are of the most overwhelming importance. He admits that the chemical reactions of the animal body are of such complexity that demonstration of the action of photochemical principles is almost impossible at the present moment, it is never practicable to isolate photochemical action from other phenomena taking place simultaneously. Professor Plotnikow does, however, point out that there is a field of great promise to medicine, as yet almost untouched, in the investigation of the photochemistry of proteins. We already know that certain foods, if irradiated, become endowed with vitamins, if we can elucidate the photochemical mechanism concerned the possibilities become limitless. The practical results of photochemistry are, however, by no means confined to biological fields. The wonders of the camera and the cinematograph are known to all. Professor Plotnikow fore-shadows a photo-electrical method of harnessing the solar energy—the evolution of a light accumulator. Already in the laboratory a mixture of corrosive sublimate and ferrous chloride can be converted under the action of light, into calomel and ferric chloride, and these bodies, re-forming in the dark the original compounds, produce an electric current. Can we look forward to a time when the sun will supply the power each day for us to turn into electric light every evening?

EXTENSIONS AT ST MARY'S HOSPITAL

THE increasing frequency of demands for the accommodation and treatment of casualty cases, arising from modern traffic conditions in London, was one of the main reasons for the new extension at St Mary's Hospital, Paddington, recently opened by Lord Iveagh. Mr A. R. Prideaux, chairman of the Board of Management, stated that the increasing number of accident and sudden emergency cases which had had to be refused admission in recent years had caused grave concern, and plans were accordingly made for an extension. The completion of this work adds some sixty beds to the hospital's accommodation, many of which will, it is understood, be utilized for casualty cases. In addition, two new operating theatre suites have been provided, and important alterations have been made in other directions. Central heating has been introduced throughout the old wards, the kitchens have been remodelled, and certain auxiliary plants have been installed. The four new wards are situated on the third floor of the centre block—one bearing Lord Iveagh's name in recognition of his services to the hospital—and the theatre suite is on the fourth floor above. Of the amount asked for in the appeal made in 1926—namely, £60,000—£52,000 has so far been received. Lord Iveagh, in the course of his address, referred to the work done in the advancement of medical research at St Mary's Hospital.

In connection with the Annual Meeting of the British Medical Association to be held at Winnipeg in 1930, the Representative Body has approved the nomination by the Canadian Medical Association of Dr W. Harvey Smith of Winnipeg as President of the British Medical Association for the year 1930-31.

INTERNATIONAL CONFERENCE ON CANCER

MELTING OF DELEGATES IN LONDON

(Concluded from page 169)

THE discussions in the International Conference on Cancer in London continued with unabated vigour until July 20th. The report in our last issue carried the proceedings up to the Wednesday morning of Conference week, when the members met in four sections, two of which have already been reported.

SECTION OF PATHOLOGY AND PUBLIC HEALTH Occupational Cancer

Professor W. S. LAZARUS-BARLOW presided over this full and interesting discussion. Dr. J. C. BUIDGE and Dr. S. A. HENRY (both of the Home Office) submitted a paper in which they expressed the view that cancer must, in order to be classified as of industrial origin, fulfil two conditions—namely, that the incidence rate in the occupation under review exceeds that in the general population to a significant extent, and that in the occupation concerned there is sufficient association of the worker with a substance proved experimentally to have carcinogenic properties. Investigation had shown that certain classes of skin epitheliomata might be definitely regarded as industrial in origin. The results of investigations in several industries, including chimney-sweeps, patent fuel workers, cotton spinners, and workers handling salts of arsenic, especially in the manufacture of sheep-dip, were given in detail. The authors added that there was only one effective solution of the difficult question of prevention—namely, the substitution of innocuous bodies for those known to have carcinogenic properties. A binding substance to replace pitch had been invented and shown by Dr. TWORT of Manchester to be non-carcinogenic to animals. Whether its use was a commercial possibility had yet to be proved. In some cases it might well be that substitution was impossible, and then the hope lay in early detection and treatment. The study of occupational cancer was a field of research which should be fully investigated in every country. Dr. T. H. C. STEVENSON also read an opening paper on the relation of cancer to syphilis and alcoholism. The paper compared the cancer mortalities of two groups of occupations, selected as of lowest and highest recorded mortality from syphilitic diseases, and showed that for each site for which the comparison could be made cancer mortality was higher than the average for the occupations of high syphilis mortality and lower for those of low syphilis mortality. Another comparison, between cancer and alcoholism (measured by cirrhosis of the liver), yielded similar but less striking results. Dr. Stevenson pointed out that the carcinogenic influence of alcohol appeared to be less than that of syphilis. The results in both comparisons seemed to point to the rule of a "Godly, righteous, and sober life," which one might well believe to be followed especially by the clergy, and to explain their relative escape from cancer.

Two papers by Dr. O. ROSTOSKI and Dr. G. SCHMOLT, of Dresden, on Schneeberg lung cancer were read by Professor ARCHIBALD LEITCH. This is a pulmonary affection due to malignant tumours of the lungs found in the bismuth, cobalt, and arsenic mining industry in Schneeberg. The fact was established that in a quite circumscribed group of men who all followed the same occupation an excessive incidence of lung tumours was discovered. According to investigations set on foot by the Saxon Cancer Committee there was no doubt that lung cancer occurred endemically among these workers, and a close connexion seemed to be possible between the lung carcinoma and the more or less intense anthracosis of the lungs from which these miners suffered. Dr. A. SCOTT (Broxburn) followed with a paper on the role of mineral oils and paraffins in the production of cancer. He recited the various conditions met with among the paraffin workers of the Scottish shale oil industry and discussed the statistics and the etiological factors predisposing to paraffin workers' cancer, the chief of which were age, length of service, and idiosyncrasy.

Regular examinations of workmen exposed to contact with substances known to be carcinogenic agents were of great value. The occupational cancer of mule spinners was the subject of a paper by Mr. A. H. SOUTHAM (Manchester), and after discussing incidence, clinical features, and treatment, he emphasized the importance of diagnosis at an early stage when operative treatment was a simple procedure. The workers should be educated to pay prompt regard to any warts or small sores on the skin.

Dr. L. CANOZZI (Geneva) dealt with the general question and pleaded for an international inquiry in the various industries involving exposure to cancer risk. Dr. A. F. SLADEN (Swansea) dealt with the occurrence of cancer in brickette workers who handled pitch which got on to a dusty floor. In every case he had seen the disease had been in the scrotum, though it was possible that it could become malignant in other parts of the skin. After the age of 35 men were more prone to develop lesions, not necessarily malignant, and long duration of exposure was a factor. Dr. W. J. O'DONOVAN (London) contributed an elaborate paper on cancer of the skin due to occupation. He mentioned in particular arsenic cancer and oil cancer, and submitted a long list of cases of carcinoma of the hand with the object of showing to what extent a recognizable occupational agent entered into the causation. The hand was the part most frequently involved in occupational cancer, and he urged that those who had performed amputations on hands should bring the cases forward, as these would be of great value to the investigations. Finally, Dr. W. M. DE VRIES described occupational cancer in his country—the Netherlands. There appeared to be few such cases except in patent fuel factories, and even here it was usually a benign papilloma that occurred and not a carcinoma.

RADIOLOGY

Biological Effects of Radium and X Rays

In the Section of Radiology, on Wednesday morning, with Professor SIDNEY RUSSELL in the chair, the subject for discussion was the biological effects of radium and x rays.

Professor C. REOUX (Radium Institute, Paris) said that experiments on the normal tissues of higher animals had shown that different tissues reacted very differently if the intensity and duration of the treatment were varied. Friedrich and Kronig showed that, given the same quantity of radiation on human skin, earlier and more marked effects were produced when the dose was given in shorter periods than when spread over a longer time. It was, however, a mistake to assume that the experimental results obtained with human skin could be applied to other tissues. In 1927 Ferroux and himself, working with x rays, showed that it was practically impossible to produce stimulus in the male rabbit without producing necrosis of the skin, whatever filter might be used. On the other hand, sterilization could be easily and constantly produced without causing any serious and lasting lesions of the integuments if one split the dose and extended it over four or five days. Thus there were differences in the behaviour of various tissues to radiations when the intensity and duration of the treatment were varied. He thought explanation must be sought in the alternation of the radio-sensitivity of the cellular stocks which were dependent on the renewal processes of the normal and neoplastic tissues. He concluded by a reference to the theoretical applications.

Professor H. HOLTMANN (Hamburg) said that certain factors must be considered in regard to dosage apart from the actual quantity used, such as the vitality of the emanation and the depth to which it was desired to penetrate. But so far, no quantitative rules had been made in regard to the quality of rays as used relative to the focus in a particular part of the body. Still, it was known that the skin-tolerance dose should not be exceeded in applying a focal dose. It had been found that the reaction of a certain x-ray dosage on human skin and pig skin within the limits of rays used in deep therapy, was independent of the quality of the rays. The effect of cumulative doses was not denied but the effect of a certain dose given at a number of sittings was greater than the same quantity given at once. Various cells recovered from the impact of rays in periods which showed considerable differences. Investigations made on single

cells were not likely to solve the problem, but they were valuable steps to further knowledge.

Dr D. QUICK (New York) spoke as a physician who dealt with cancer, and his object was to show some correlation between the experimental data arrived at and clinical findings. Much valuable information had resulted from the method of trial and error. Too much was assumed from purely physical measurements, and he asked whether it was quite established that the rays calculated were actually absorbed. Was the action a purely chemical one, or did ionization enter largely into it?

Dr GUSTAV BUCKY (New York) emphasized the peculiar appropriateness of the skin for investigation of the effects of radiation on living tissue, it possessed a variety of functions, and had several layers superimposed on which the separate effects of rays could well be judged. He showed on the screen, in graphic form, the effects on the skin of radiations respectively of 100, 60, and 30 kilovolts to a depth of 1 mm.

Dr R. G. CANNI (London) discussed the relationship of radiation in time and intensity, basing his remarks on work which had been done at Cambridge University. He set out the various time and intensity thresholds which must not be passed. For cancer it was clearly better to use weaker intensities of radiation over a considerable time than a concentrated emanation for a short time.

Dr N. S. FINZI concentrated attention on the latent period, which was important as a means of discovering the mode of action of the irradiation. He defined the latent period as the space of time after the application of radiations before some of their effects became obvious. The latent period depended on several factors, which he detailed.

Other speakers were Professor LAHM (Chemnitz), Dr L. MALLET (Paris), Professor FRANCIS WOOD (Columbia University), Dr S. N. WATERMAN (Amsterdam), Dr A. PINEX (London Cancer Hospital), Professor DYNE (Harvard) who pleaded for uniformity of definitions of intensity, Dr W. C. STEVENSON (Dublin), and Dr SPENCER MONT (London).

RELATIVE VALUES OF SURGERY AND RADIATION

The general discussion on the relative values of surgery and radiation in the treatment of cancer of the cervix, uterus, rectum, breast, and buccal cavity, which was opened on Tuesday morning, July 17th, as reported in our last issue (p. 106), was continued on July 19th, under the chairmanship of Mr J. P. LOCKHART-MUMFERY.

Cancer of the Breast

Professor BURTON LEE (Cornell University) opened with a plea for conservatism in the treatment of primary operable cancer of the breast. He gave tables showing a higher percentage of satisfactory five-year results after irradiation and conservative surgery than were produced by radical amputation, preceded and followed by x-ray therapy. He considered that irradiation in conjunction with conservative surgery justified itself as a therapeutic method in dealing with this disease. Mr SAMUEL HANDLEY submitted as his conclusion that surgical operation in breast cancer still remained a necessity for removing the bulk of the growth and reducing the problem of the radiologist to manageable proportions. For the present, at any rate, surgery and radiology must be colleagues, not competitors. To use either means alone was to fight a dangerous antagonist with only one hand. Dr ROBERT KNOX suggested as a possible grouping of cases: (1) early cases with no metastases detected in the glands, (2) cases with definite metastases in the glands, but no deep seated involvement, (3) advanced cases. In a small number of patients treated at the Cancer Hospital by x-rays after operation, those in the first class alive after five years numbered 71.4 per cent. in the second class, 53.6 per cent. and in the third class, 9.1 per cent. It was, in the second class that radiation treatment appeared to have the best advantage over operation alone. He contended that the combined method offered the patient the best chance of recovery. As for inoperable cases there was no question at all as to the immense value of radiation.

Mr G. GOTTFRY KAYNES said that during the past four years the surgical unit at St Bartholomew's had applied radium to 42 patients with primary carcinoma of the breast. The method of treatment had been to bury radium needles beneath the tumour and in all the accessible areas of lymphatic drainage. At first only patients unsuitable for operation were treated, later the number of cases in an operable condition was increased. Of the 42 patients, 17 were inoperable, 22 operable, and 3 doubtful. Among the inoperable cases six had died of metastatic growths. Two other patients had died of intercurrent disease, and of the 34 patients alive, 13 were apparently cured, 15 had been too recently treated for any judgement to be formed, 2 showed metastases, and 4 recurrences. He thought Mr. HANDLEY's position a little illogical, for Mr. HANDLEY acclaimed the radium method, and yet seemed unwilling to trust to it in primary carcinoma of the breast. Dr J. H. DOUGLAS WENSTER agreed with Professor BURTON LEE that there was not quite sufficient recognition of the unique value of radiation in breast cancer. Radiation treatment could, frankly, make inoperable cases operable, it could also sterilize the operation area, pre-operatively or post-operatively. He thought there was much to be made out in favour of pre-operative radiation.

Cancer of the Buccal Cavity

The final discussion was opened by Dr DOUGLAS QUICK (New York), who said that radiation should be regarded as an additional surgical equipment, not as an opposite to surgery. The experience of his hospital was that radium was preferable to x-rays, and, lately, filtered radon "seeds" had been employed in the treatment of carcinoma of the buccal cavity, with good results. Out of 2,741 patients in whom radium had been used in cancer of the buccal cavity in the course of eleven years, 1,346 were known to have died, and others had been lost sight of, but 780 of the patients were now included in a follow-up system, and of this number 602 were free from any gross evidence of disease. He added that applicators within the month had no value.

Mr STANFORD CADE said that the superiority of radium treatment was such that, so far as the primary growth was concerned, it was, in his opinion, the only method which combined both safety in the actual performance with the best results to be obtained, and this without mutilation. Surgical treatment had given results so indifferent that those obtained by radium appeared brilliant. In operable cases the immediate results were so good that, given the correct technique, this newer and more humane method ought gradually to supersede the older. As regards final cures, periods of five years had now been passed. In his own experience patients were alive and well as long as four years after the treatment, so that it could be confidently expected that ultimate results would be as gratifying as the immediate alleviation offered to the patient. Fifty cases of oral cancer had been treated during the last four years, either by himself or jointly with his colleague at the Westminster Hospital, Mr. Arthur Evans. From a study of these cases it was evident that the treatment of malignant disease of the oral cavity comprised three stages: (1) radium therapy of the primary growth, (2) surgical removal of the cervical glands, and (3) post-operative distance irradiation of the cervical area. Dr G. E. PFAHLER (University of Pennsylvania) said that during the past few years he had been treating carcinoma of the mouth according to the principles laid down by Regaud—namely, that a moderate amount of radiation continued over a considerable time was better than a great amount of radiation given in a short time. As the radiation became more penetrating the diffuse necrotizing effects diminished, then practically disappeared, and finally only the selective effects remained which were manifested in the most radio-sensitive cells, which were the cancer cells in the process of division. Dr PFAHLER had accordingly filtered the rays from radium through the equivalent of 3 or 4 mm. of lead, and prolonged the effect over three or four weeks. The results had made him enthusiastic, and he believed that, taking the average of cases as they first came to the physician, there should be a fifty per cent. chance of cure with thorough and skilful treatment by the harder gamma radiation. Dr B. T. ROSE

(Birmingham) described some work in the Radium Department of the Birmingham General Hospital on lincal and rectal cancer. As to the relative values of surgery and radiation in the treatment of the former, it would appear that both methods were often requisite in a particular case. A growth of the tongue or floor of the mouth which was frankly inoperable was undoubtedly best treated by radium, in an operable growth he thought the choice should be for local excision with the diathermy knife and subsequent irradiation of the scar.

Evaluation of Statistics

Dr JANET LANE CLAYTON (Homo Office) contributed a useful paper on the evaluation of statistics relating to effectiveness of treatment, and mentioned a number of the improper uses frequently made of numerical statements, and the fundamental necessities which should be laid down for any statistical inquiry. The paper was full of illustrations of possible fallacies in the handling of statistics. One, for example, was the so-called "cancer age." It was stated in a number of medical textbooks that cancer of the breast was most prevalent in middle life, and ages were given of patients attending hospital and found to be suffering from this condition. But if the deaths from cancer of any site, or of cancer in general, were compared with the total number of persons alive at that same age, it would be found that the death rate was greater in old age in proportion to the population than in middle life. The explanation of the discrepancy was due to the fact that the actual number of persons alive was greater at middle life, and that after middle life persons ceased almost entirely to make application for operative treatment.

The paper was discussed briefly by Professor JUNGLE (Stuttgart) and Dr CARTER WOOD (New York), the latter pointing out the fallacies underlying group statistics unless pains were taken to grade the cases, not only with regard to the anatomical extent of the tumour, but also to the histological character.

Methods of Treatment by Chemotherapy

A general discussion was held on Thursday morning, July 19th, on methods of treatment by chemotherapy, with special reference to lead, when Sir THOMAS HORDER presided.

Professor BLAIR BELL (Liverpool), in an opening paper, defined chemotherapy as treatment by synthetic preparations having a selective therapeutical action on abnormal tissues of the body and on the organisms which might infect it with or without the production of associated constitutional phenomena. He was one of those who believed that malignant neoplasia was a specific growth-process (dedifferentiation) initiated by many predisposing factors. This reversionary process was directed towards the trophoblastic type, perhaps through, rather than to, that of the embryonic somatic anlage. Hence the adult somatic cell which underwent dedifferentiation passed back through the later stages of somatic development before reaching the primitive type, with the result that malignant neoplasms varied considerably in the degree of dedifferentiation they had undergone, and the most malignant tumours were those in which dedifferentiation was greatest. After some elaboration of this point, Professor Blair Bell went on to say that every chemotherapeutic agent employed in malignant neoplastic disease should have two attributes at least—namely, the power to arrest cell growth generally, and a special affinity for malignant cells and the chorionic epithelium. It had long been known that lead arrested growth generally and caused abortion. He and his colleagues had demonstrated that lead in suitable doses caused coagulation necrosis of the chorionic epithelium, and that abortion was the result of this rather than the sequel to intrauterine haemorrhage of toxic causation. After treatment lead might be recovered from malignant neoplasms in considerable quantity. No very definite conclusions had as yet been reached as to the way in which lead acted on normal growing tissues and on malignant cells, but it appeared possible that the action in regard to cancer was both local and constitutional. A further point was that cancer cells resembled in many ways morpho-

logically and functionally the cells from which they were derived, so that it followed that the less dedifferentiated the cells the more they would resemble the cells from which they arose. It seemed, therefore, that in the synthetic preparation of any chemotherapeutic substance, such as a lead complex, not only should the specific action of the remedial agent in regard to growth and the malignant cell generally be taken into account, but also the special chemical constitution, function, or evolvable reactions of the differentiated (specialized) tissue in which the malignant neoplasm had developed. If it were found possible to make on these lines a preparation of lead which was absolutely specific for any one well defined type of malignant growth it would appear that the lead preparation used should vary according to the original tissue from which the neoplasm had sprung. In conclusion Professor Blair Bell said that although it had been found that lead was detrimental to the cancer cell, just as arsenic was well known to be to the spirochaete, there was still much work to be done, and on that account he would not repeat the analysis of his clinical results, which would be informative only in respect of the beneficial effects observed. He believed that the consensus of opinion would bear out the statement he made in 1922 that the effects of radiations were augmented by the previous use of lead. The employment of lead as a prophylactic measure against recurrence after surgical operations for cancer would, he thought, be held to be of great value. Finally there was a considerable body of evidence to support the view that by itself lead, even in the crude preparations now used could cause the disappearance and apparent cure of malignant neoplasms in favourable circumstances, and sometimes could beneficially affect leukaemia and other neoplastic conditions.

At the conclusion of Professor Blair Bell's opening the CHAIRMAN (Sir Thomas Horder) said that he could have wished Professor Blair Bell had said more about practical therapeutics, but perhaps speakers would so concentrate their remarks that Professor Bell could deal with the points in his reply.

Professor CARTER WOOD (Columbia University) related his experimental studies in lead therapy. About a year ago he published some experiments pointing to the conclusion that with one type of tumour a distinct advantage was gained by a combined administration of x rays and lead. Another—a highly malignant sarcoma of the rat—was not benefited by this combination. Mottram had recently shown that a combination of radium and lead was better than either used alone. Recent experiments in the Crocker Institute on colloidal lead and gold bore on the same question. Colloidal gold was administered as against lead because of the lack of toxic action in the former on the cells. With colloidal lead the tumour was often converted into a haemorrhagic sac, the wall of which was composed of a smudged border of living cancer cells in contact with the normal connective tissues. The experiments he related showed no evidence that lead alone could cure a rapidly growing animal tumour, yet there was a distinct advantage in continuing to study the action of the drug. In the case of the Flexner-Jobling rat tumour the best effect was produced by giving x rays first and following that with repeated doses of lead, beginning four or five days later. The fact that tumours did not alter in size under treatment did not prove that they had not been influenced, as they might well be much less malignant though as large.

Professor W. J. DILLING (Liverpool) said the success being achieved by Professor Blair Bell and others by using lead alone or by radiation, was much greater than could be explained by spontaneous arrest or other cause. He expected a substance to be hit upon which would prove to be more effective than lead but he did not expect a panacea of any kind for cancer. The aim of workers was to find a something which would retard the progress of the malignant cell without damage to surrounding tissues. In cases examined the tumour contained more lead than other tissues did.

Mr BASIL HUME (London) spoke of treatment carried out strictly on the Blair Bell method at St Bartholomew's Hospital under a committee of the college (Professor Blair Bell visited the institution and expressed his full approval

of the method) The conclusions derived were highly unfavourable to the method being tested, though in some of the patients the disease was in a comparatively early stage. All were far from moribund when the treatment was commenced. If they had not been so treated their average expectation of life should have been far greater than the thirteen weeks average they lived. The cases afforded no evidence that the use of lead by intravenous injection led to the resorption of neoplastic tissue in the human subject. In several of the patients grave ill health commenced as soon as the treatment had been begun. No evidence was forthcoming, either, that the type had been changed to one of less malignancy. Yet none of the patients had died as a result of acute or chronic lead poisoning.

Dr STANLEY WYARD (Cancer Hospital, London) said that most observers seemed to agree that there was no greater amount of lead in the tumour after this treatment than in the neighbouring tissues. Without any personal bias, he had tried the effect of colloid lead in a series of inoperable, but not moribund, patients. Of 40 who received sufficient lead 23 died, 10 were worse, 6 showed no change, and only one in any way improved. His own conclusion was that lead was of absolutely no value in the treatment of malignant disease, there seemed no reason for regarding it as effective, and there was no evidence that it was effective.

Dr LORAIN (Paris) gave the results of his experimentation with lead in combination with glycogen, and of the treatment of 21 cases with it. In 4 there was an arrest of the tumour following the treatment.

Dr A. P. THOMSON (Birmingham) said that among 55 cases treated with lead that drug seemed to have a favourable influence on the disease in 15. Even in those, however, the improvement was only temporary. In his experience, colloidal lead had yielded better clinical results than either lead glycine or colloidal lead phosphate. He gave details of all the cases, in one or two of which there was a dramatic improvement.

Dr H. J. B. FRI (London) described the *post-mortem* changes he found in various organs and tissues in patients who had undergone the lead treatment. The chief changes were in the kidneys, liver, spleen, and brain. In the kidneys probably the changes were due to the selective action of the lead on the convoluted tubules.

Professor BLAIR BELL, in reply, contended that little was said in the discussion on the principles of chemotherapy involved. The primary question was as to what advice should be given to patients. In Liverpool they had never allowed a scientific curiosity to outrun humanity, and for that reason they had not restricted their inquiry and their efforts to lead. Many of the 1,000 cases treated had had lead alone and a considerable number had that in combination with deep x-ray therapy. Others had had lead and radium combined. Many patients who came to him from London had been given a harrowing account of the sufferings the treatment entailed, but the truth was it was now known how to prevent that suffering. He did not wish to make further comments on the report from the Cancer Hospital, his comments would be found in the *British Medical Journal*, he apologized to his colleagues for having had to speak so plainly, but misrepresentation of the work going forward at Liverpool could not be allowed. He did go to St Bartholomew's Hospital, but the report of that institution was based on only 20 cases, and 15 of those 20 received only half the proper treatment. That was not the fault of Mr. Hume, it was simply that the patients were too ill, and died before the treatment could have a proper chance. Admittedly, it was at present a crude treatment, but it was along a line which, he hoped, would eventually lead to a considerable lessening of cases of the disease which was afflicting so many fellow beings.

The general discussion was continued by Dr T. LUXSDEN (of the Lister Institute), who spoke of tumour immunity and vaccine treatment. He said that antimalignant cell bodies could be produced which had a specific affinity for cancer cells, they attacked and killed the cancer cells without damaging normal tissue cells. After using vaccine, the immunity was much higher than otherwise. He suggested that those who were treating tumours with radium should not be in a great hurry to get rid of the local growth so as to cause sloughing, because this would prevent the

intense of immunity. He offered to demonstrate the reactions spoken of to any who would visit the Lister Institute.

Dr MONCKTON COLFMAN spoke of the enhanced effect of irradiation after painting the surface with activated shoeesin. This was an absolutely non-toxic substance, and the effect of its use was that a much enhanced effect was produced on the malignant cells. Dr I. D. M. HOCKING (London) described his work on uranium and thorium, and advocated research on mixed colloids in relation to the treatment of cancer. Dr PELCZAR (Cracow) referred to his research into the action of certain lipoids and albumins, and the diminution of tumours into which they were injected.

St. Thomas Hospital's Summary

The CHAIRMAN, in closing the discussion, said that there were three questions which might be asked: (1) Had any patients got well after treatment with lead? The answer to that question, as evidenced by the morning's discussion, was in the affirmative. (2) Had the evolution of the treatment reached such a stage that it had become a practical measure of therapeutics for unselected cases—in other words, could the medical man undertake the responsibility of advising his patient to undergo treatment? To such a question some in the discussion had answered "Yes" and others "No." There was no occasion to be unduly troubled by this lack of unanimity, which was common in the history of many remedies, whether they had ultimately emerged successfully or had been abandoned, but in discussing any method of treatment it was necessary to consider, not only the value of the remedy, but the technique of its administration. The man with the largest experience would for a time after the introduction of a remedy get the best results from it. This might be entirely independent of any undue enthusiasm and consequent bias, but such a position could only be a temporary one. Very soon, if the remedy was really one of value, the results would be obtained by all who took the trouble to master its technique. As to how far this consideration applied to the present position of the lead treatment of cancer, he felt it invidious to judge, but it was an important consideration, and the responsibility he had just referred to must be discharged by the practitioner himself, in whose judgement the patient put his confidence. They could not yet, as a result of that discussion, relieve him of his personal responsibility. It must be clear that no remedy was a practical remedy where the margin of safety between its lethal effects upon the vital tissues and the resorptive effects upon the growth was less than that which admitted of reasonable control. Had the preparations of lead at present available passed that level of practicability? He was not sure—he was speaking personally—that this was not the crux of the position. He felt that they had not yet arrived at the point of safety which would enable them to advise their patients in this direction. One patient, an old pupil of his, declined to proceed further with the lead treatment on account of the very great malaise which the injections produced, and this was one of the cases in which x-ray treatment proved of considerable benefit. This might only mean that the London technique was different from the Liverpool technique, and it might involve one of those fallacies which in such a complex subject were always with them. (3) The third question was: What were the steps it was desirable to take in regard to the non-operable treatment of cancer in the further exploitation of chemotherapy with special reference to lead? In the first place, surely animal experiments should continue, with the proper scientific controls which were usual in laboratory work. Secondly, still further research should be undertaken in the preparation of a lead compound less toxic in its effect than those which had been used, so that the margin of safety might be widened. He did not mean that an entirely non-toxic product need be forthcoming, in such a product he would have little faith. If a drug was not a possible source of danger to the patient it was difficult to believe that it could be productive of any great good. Too much must not be asked for in the way of removal of the toxic principle in therapeutic measures. Thirdly, they need not, so to speak, put all their eggs in one basket, they had to get on with the treatment of

the patient. Surely it was not necessary to change over entirely from measures of known value to measures of unknown value, in other words, they should combine methods of treatment in these cases, and thus, he personally thought, was a very hopeful line to take—to use, perhaps lead, perhaps a variety of these products, in combination with radiation. There was need for a wide horizon, no light should be neglected. All concerned should keep cool and deliberate, to use a political expression, they should “explore every avenue.” If research was pursued patiently and dispassionately a goal would be reached which would justify that morning’s discussion.

SECTIONAL DISCUSSIONS

Friday, July 20th

On the closing day of the Conference it again met in four Sections

Early Recognition and Treatment of Cancer of the Stomach

In the Surgical Section, over which Sir CHARLES GORDON-WATSON presided, Sir BERKELEY MOYNIHAN opened a discussion on this subject. He said that it was to the earlier recognition of cancer of the stomach that attention must be directed. So many patients arrived at the operation table far too late to allow even the most resolute surgeon the opportunity of giving permanent relief. He emphasized the striking diversities found in the disease. If symptoms were so multiform, and therefore so misleading, that sufferers did not seek relief in the curable stage what was to be done? Cancer here and everywhere was at first a local disease, and if it was removable a cure of the condition was possible. There were no symptoms pathognomonic of carcinoma in any of its stages, the symptoms were only suggestive, not conclusive. The success of medical treatment in early cases of cancer of the stomach was one of the causes of the very high mortality of the disease. It was not relief but knowledge that was wanted, and instead of seeking to subdue symptoms, one should seek to evoke them. The main inquiry centred upon the radiologist, whose approach to accuracy, though he was not infallible, was far greater than that of the clinical physician. When the radiologist was in doubt, it was for the surgeon to decide by inspection of the parts. Intemperate exploration was to be condemned. Only after the fullest, most earnest, and repeated inquiry was such a procedure to be undertaken. Examinations by the radiologist, and by the chemist for free hydrochloric acid in the stomach contents and for blood in the faeces must be insisted upon if the present lamentable condition of things in regard to the surgical treatment of gastric carcinoma was to be improved.

Dr A F HURST adduced a number of cases which led to the conclusion that achlorhydria was not the result of carcinoma of the stomach, but preceded its development, and he expressed the view that the large majority of cases of achlorhydria were due to chronic gastritis, which had been shown to be present in almost all cases of carcinoma of the stomach. Dr EDWARD SPRINGS (Ruthin Castle) thought that radiology and chemical tests introduced the danger of giving less time and attention to clinical inquiry. In every case an endeavour should be made to form a diagnosis on clinical evidence, though all other means should be used, especially radiology. He gave particulars of the early symptoms in a series of patients with cancer of the stomach, and said that it was wrong to treat indigestion for any length of time in a middle-aged person without taking steps to exclude cancer. Professor H FINSSTADT (Vienna) dealt with the immediate and permanent results of the resection of the stomach for cancer. He advocated radical operation, with removal of the greater omentum and the entire lymphatic area of the tumour. He considered the removal of the greater omentum particularly important, as he had had to carry out a number of secondary operations for local recurrence in the greater omentum in cases operated on by other surgeons. Professor M J STEWART (Leeds) analysed a series of 239 stomachs or portions of stomachs removed surgically, and pointed to a history in many of the cancer cases strongly suggestive of chronic ulcer. He also emphasized the importance of multiple adenomatous polypi as a

pre-cancerous condition. Mr A J WALTON said that many carcinomas were curable if subjected to early surgical intervention, but carcinoma of the stomach was one of the most unsatisfactory varieties, for early diagnosis was associated with much difficulty, and the late prognosis was not nearly as good as was at one time believed. It was therefore all the more satisfactory to notice that there was little or no evidence that the disease was on the increase. In his own series of cases there was definite evidence that a certain number of cases of carcinoma had started as chronic ulcers. The hope for greater success lay, not only in a wider recognition of the early symptoms of carcinoma, but also in the subjection of chronic ulcers in patients between 40 and 60 to early operative treatment, instead of a long period of medical treatment. Professor D P D WILKIE (Edinburgh) advocated periodical medical examination as the surest means of obtaining early diagnosis. The employment of a barium meal x-ray examination in all cases of obscure ill health would reveal early carcinoma of the stomach when this was present, though clinical signs and symptoms were still indefinite. But no single test was infallible. Mr H W CURSON said that the symptoms, such as pain and vomiting, which brought a patient to his doctor were late and not early symptoms. He believed the first of the symptoms to be loss of appetite, and the second loss of energy, followed by some anaemia and slight loss of weight.

Professor RAFFAELE BASTIANELLI (Rome) gave a brief review of personal experience of 543 cases of cancer of the stomach. These included 239 resections (mortality 28 per cent), 176 gastro-enterostomies (mortality 21.5 per cent), and 118 explorations (mortality 15 per cent). He explained that he did not seek to find reasons for his mortality figures, a great deal depended on the sort of case a surgeon would operate upon. His guiding principle was to remove the stomach as often as the anatomical conditions would allow and as extensively as possible. A great part of the operative mortality was due to thoracic complications. For several years he had employed local anaesthesia in gastric operations, giving only a general anaesthetic in addition when the case demanded it. He favoured a Polya-Reichel technique, employing only Billroth I in exceptional cases, for the former gave the best chances for an extensive successful operation. Special attention was paid to the smaller curvature. A study of the recurrences was important in determining the extent of an operative technique, and a general routine ought to be adopted in all advanced cases. Professor Bastianelli did not think that the ovaries were affected from stomach cancer by cells dropping on to their surface, but the invasion occurred from the hilus by lymphatic spread. Surgery was only one part of treatment, it could not be expected to improve much further. It was no exaggeration to say that with the most hopeful surgical technique at present it could not be expected that more than 7 per cent of patients with stomach cancer seeking advice would be likely to be cured. It was therefore necessary to study the precancerous lesions and use preventive surgery, and the earliest symptoms of cancer must be recognized. Professor Bastianelli discussed these symptoms and signs.

Sir BERKELEY MOYNIHAN, in replying on the discussion, urged the simplification and cheapening of methods to make them more accessible to the public. This was a State problem, and he thought some representation to the Government from the Conference might have effect. Under the national health insurance scheme greater facilities should be given the general practitioner for radiological and laboratory assistance, while representations might be made to insurance companies to reduce the premiums to persons, especially the middle aged and elderly, submitting themselves to periodical medical examination.

Diagnostic Methods in Relation to Cancer

In the Section of Medicine, Diagnosis and Pathology, over which Sir WILLIAM HALE WHITE presided, the discussion was on diagnostic methods.

Sir THOMAS HONNER, in opening, said that so long as the effective treatment of cancer rested with the surgeon and the radiologist so long was its success directly dependent upon early diagnosis. The significance of dyspeptic

symptoms arising in adults previously free from them could scarcely be over-emphasized. He did not, however, agree that the disease had a predisposition in ulcerations, displacements, motor defects, and other types of dyspepsia. That was contrary to statistical facts. In speaking of "abdominal exploration" he wondered if his surgical colleagues might not be defeating the object of diagnosing cancer in its very early stage by insistence upon the complete ritual of the operating theatre whenever a small incision was made for the purpose of ascertaining the nature of a doubtful lump or other abnormality. The ritual, and the alarming drama that so frequently attended it, made exploratory laparotomies exceedingly unpopular with the patient and added greatly to the physician's difficulties in the event of his decision to advise such procedure. As to instruments used in diagnosis the speaker entered a plea for the more frequent use of the sigmoidoscope, the cystoscope, and the laryngoscope. Of late years radiology had, without question, proved the greatest addition to diagnostic methods. That great care and much forbearance were needed in the interpretation of radioscopic shadows went without saying. The fallacies and pitfalls in the science were admitted even by the most expert. Nevertheless, the value of the method was already scarcely calculable, and must tend to become even greater as experience and invention increased. Biopsy was a method of diagnosis that approached nearer to certainty, perhaps, than any other, but, again, only the expert realized all the fallacies. That form of biopsy termed the "fresh section" taken in the operation theatre was notoriously more open to error in the hands of all except the very experienced. Serology was still in its infancy so far as cancer diagnosis was concerned. It might never grow to full stature because the stage of cancer development at which diagnosis was imperative was that before which blood changes were to be expected. Nevertheless, it would be foolish to set a limit to serology or to the methods of haematology and biochemistry. One never knew, in the history of a malignant growth, when changes might occur in the blood and tissue fluids which, though they might escape clinical detection, might yet not escape the keen eye of the pipette or the test tube.

Dr T. IZOD BENNETT (London) confined his remarks to the diagnosis of cancer of the stomach. Indisputably x-ray examination, both by the screen and by x-ray photography, constituted the method of first choice in all cases of carcinoma, but it had to be remembered that occasionally benign tumours, or even syphilitic lesions, would give x-ray appearances quite indistinguishable from those of cancer. Much confusion existed in the minds of medical men as to the actual value of gastric analysis in the diagnosis of cancer of the stomach, but the speaker said that after many years' experience he had come to the conclusion that a carefully performed gastric analysis yielded a reliable diagnosis in considerably more than 90 per cent of all cases. It was more than fifteen years since gastroscopy as a means of inquiry had been introduced in London, and it had to be confessed that up till now its results had been somewhat disappointing. Probably in ten years' time it would become as rare for a surgeon to perform an exploratory laparotomy without gastroscopy as it was now for the bladder to be operated on without preliminary cystoscopy.

Dr MACCARTY (Mayo Clinic) asked what was meant by early diagnosis of cancer? Did early cancers give textbook signs and symptoms? They did not. No cancer in any part of the body was early if larger than half a centimetre in diameter. Did the general post-mortem pathologist see early cancer? He did not. Early cancer did not kill the patient. In attempting to discover early stages were there any specific diagnostic methods which could be used? If in the absence of specific diagnostic methods physicians waited for classical symptoms, then they might just as well cease urging the public to come early to them. Professor L. S. DUNGEON (London) described the wet film examination of new growths, the technique of which was based on Schaudinn's method. It was, by that method, comparatively easy to distinguish between malignant and benign growths, the carcinoma cell appearing very much larger than the benign. Professor W. C. M. LEWIS (Liverpool)

dealt with the influence of normal and cancerous blood serum on pancreatic lipase action and the effect of lead threonon. While admitting that the method was not necessarily diagnostic of cancer he thought it of undoubted value in estimating the severity of the lesion and rate of progress. Dr H. J. B. LIND dealt with a flocculation reaction for the serodiagnosis of malignant disease, and Professor M. ASCOLI (Catania), in the course of some general remarks on serum diagnosis of malignant disease, expressed surprise that the Conference was apparently taking so little interest in such diagnosis. In his view it was only possible to diagnose early cancer by a careful study of blood changes. Professor E. C. DODDS (London), on the other hand, detailed the result of observations he had made in conjunction with Dr W. LANSON on methods for the diagnosis of cancer by a study of the blood, and took it that the fact that no one had mentioned the Abderhalden reaction and its modifications was an indication that that reaction was dying the death it deserved. The Shaw-Mackenzie reaction, as well as the Ringold method, had been investigated, and proved to be non-specific. Dr K. ICHIKAWA (Sapporo, Japan) discussed a method for the early serodiagnosis of cancer by means of the reaction of Botelho. Dr J. A. BRAXTON HICKS described experiments carried out by himself and Dr F. D. M. HOCKING aiming at the evolution of a "complement-fixation test" for cancer, which, however, had had to be abandoned owing to the inconclusiveness of the results. Dr STANLEY MELVILLE discussed the diagnosis of intrathoracic new growth from the radiological standpoint. He thought primary sarcoma of the lung exceedingly rare, the most common malignant growths of the lung being carcinomata. In his opinion the greatest aids to the diagnosis of lobe carcinoma were the production of an artificial pneumothorax for diagnostic purposes and intratracheal injection of lipiodol.

Sir WILLIAM WILCOX, in closing the discussion, added points he regarded as of undoubted value in diagnosis of cancer of the stomach, and said that the presence of a lump did not necessarily mean that the case was one of carcinoma. In the chemical diagnosis of carcinoma of the stomach it was well to remember that one of the early signs was a rapid falling off in the ferment activity. Further, it was necessary to decide in cases of carcinoma how much active hydrochloric acid was present in combination with protein, and for that reason he preferred the results of analysis of an ordinary test meal to the fractional method of examination. Another point to bear in mind was that in carcinoma of the stomach the percentage of inorganic chlorides was much increased.

The Effects of Radium and X Rays on the Blood-vascular and Lymphatic Systems

In the Section of Radiology, over which Dr ROBERT KNOW presided, the subject of discussion was the effects of radium and x rays on the blood-vascular and lymphatic systems, with special reference to malignant growths.

Dr F. CARTER WOOD (Columbia University) said it had long been known that radiation caused a thickening of vessel walls, and the changes in them, following radium and x rays, were clear-cut and interesting. Whether the tissue starvation following the partial or complete closure of vessels on irradiation was the cause of neoplastic changes in the skin following prolonged use of the rays had not been settled. Exner had pointed out that years after radium treatment a tumour might recur, he had himself seen epithelioma of the lip recur thirteen years after a radium cure. He regarded these vessel changes as among the most important factors in the arrest of cancerous growths by irradiation.

Dr A. LACASSAGNE (Paris) asked what part was played by circulatory changes in the regression of irradiated cancerous tissues. It might be due to lack of nutrition to the growth owing to obstruction in the capillaries, but he doubted this hypothesis, especially as attempts at ligation of a cancerous growth failed to arrest it, also because cytological changes, analogous to those seen in regressing malignant tissue, were present in normal tissues after irradiation. With regard to lymphatic vessels, irradiation with cancer-sterilizing doses was capable of disturbing lymphatic circulation, as shown by the local oedemas seen. He con-

sidered that the death of the cancer cells (an absolute necessity for cure) was brought about by direct action of the radiation on the cancer cells themselves.

Professor HOLFELDER (Frankfort-on-Maine) said that it was the vascular and lymphatic systems' reaction which prevented more than a particular dose of rays being given. The aim in radiating should be to act as strongly as possible on the tumour cells while saving the vascular systems. Hence the method should be chosen which exerted the greatest selective effect on the tumour cells—that is, safeguarding surrounding tissues and blood vessels. Yet he agreed with Ewing that practical irradiation acted largely through vascular disturbance. The slow progress of the lymph stream was a cause of depositions of cancer cells being found in lymphatics when metastases had occurred, when none were present in blood vessels of the part. Wintz of Erlangen had directed attention to the favourable effect of a heavy radiation previous to amputation of the breast in the prevention of lymphatic metastases. He asked that reliable figures might be compiled by different workers as to the biological effects of a given amount of irradiation, administered by various methods, such as those of Alberti and Politzer. Much importance was attached to a wide exchange of clinical experiences.

Mr CLIFFORD MORSON, speaking as a surgeon who employed radiology, gave the results of his fifteen years' experience on the effects of irradiation on the blood vessels. A very large dose of radium could cause extravasation of blood, while a smaller dose caused obliteration of the lumen without a rupture of the walls. Angioma could be caused to disappear by appropriate radium treatment, while malignant growth of blood vessels (endothelioma) could be destroyed by irradiation. The greater the vascularity of the organ in which the tumour was growing, the better were the results from the application of rays. Dr DOUGLAS WEBSTER said that huge doses of irradiation were needed to damage cancer cells directly, not only was the cancer cell to be thought of, but also the connective tissue stroma in the growth, and the blood and lymphatic distribution. It was difficult to devise experiments which would settle the fourfold factor present in malignant disease. Professor HOLTHUSEN (Hamburg) asked that the functional side of the problem might be kept in mind, and the fact that the reactivity of blood vessels altered in tissues which had been irradiated, and in those subjected to ultra-violet light. Hence erythema was not always a true indicator of the damage done by rays on the cells.

Dr WALTER STEVENSON (Dublin) gave some clinical experiences, and Dr F. T. BURKITT discussed the direct action produced on blood by purely gamma rays of irradiation, one result being the setting up of aplastic anaemia, especially in those continuously working with radium. Dr PRAHLER (Pennsylvania) said he was convinced that fibrosis, telangiectases, and necroses were the result of cumulative effects of γ rays, rather than of a single massive dose. Dr W. LEVITT spoke of a series of 34 cases of inoperable malignant disease which he had treated by α rays in an intensive way, all the patients being now apparently free from any signs of malignant disease. In all of them there had occurred a rapid decrease in the lymphocyte count.

The CHAIRMAN (Dr Knox) said that, quite correctly, most importance was attached to the direct action of the rays on tumours. But in the past the indirect action had been largely neglected or given too little weight. For some years he had himself given considerable attention to that aspect, and now he had been able to organize a research of a comprehensive nature, the blood having been selected as the tissue for the preliminary examination. Ahead of important points were emerging, and several times he had felt satisfaction that he had had systematic blood counts made in his cases. It would prove to be a valuable guide to dosage. A drop in the number of lymphocytes could be taken as an indication to "go slow" with radiation treatment.

Geographical and Racial Prevalence

In the Section of Statistics and Public Health, presided over by Dr F. E. FREEMANTLE, M.P., the discussion was on the geographical and racial prevalence of cancer. Professor M. GREENWOOD pointed out that comparisons

between races widely separated geographically were not always conclusive or reliable. After indicating certain differences in the mortality rate in various countries, he said that at present there was not enough information available to provide any explanation of such differences as that, for example, the rate of mortality from cancer of the female reproductive organs was very much higher in the Netherlands than in England and Wales. Professor Greenwood also read two papers by foreign members. One of these, by Professor ALFREDO NICEFONO (Naples), set out a number of errors frequently made in the study of cancer mortality by means of demographic statistics, and the other, by Professor PITTARD (Geneva), suggested that it was not possible to consider the soil on which a disease might establish itself as devoid of interest in etiological research. The author thought the higher cancer mortality in London as compared with New York might be due to the higher proportion in London of the Nordic type. Dr PERCY STOCKS (London) set forth the evidence for a regional distribution of cancer prevalence in England and Wales. He drew the deduction that as the mean cancer indices of the county areas varied over such wide limits, and the counties grouped themselves into such definite regions of high and low prevalence, there could be no question but that geographical influences were in some way concerned.

Dr SOUNASKY (London) dealt with the incidence of cancer among Jews. The total mortality from cancer in Jews varied among different Jewish communities in much the same way as among non-Jews of the same areas, in other words, it had a geographical rather than a racial distribution. But cancer of the uterus was low among Jewish women, not, he believed, as the result of any degree of racial immunity, but of environmental factors operating in their lives. Dr MATTHEW YOUNG said that if there was any relationship between the cancer mortality and the prevalence of brachycephaly in the different regions of Scotland, it appeared to be an inverse relation and not the direct one which was supposed to exist in various European countries.

Public Action in Regard to Cancer

Sir GEORGE BUCHANAN gave an account of the work of the Ministry of Health, the Departmental Committee on Cancer, the work in this direction of the League of Nations, and the increasing number of voluntary agencies. Though the public work done in this country might appear to be meagre, it had in it the elements of useful development on almost every side. Professor MAIRIN (Louvain) urged the establishment in every country of anti-cancer centres for treatment, research, instruction, and propaganda. The methods of the American Society for the Control of Cancer were explained by Dr G. A. SOPER (New York). These included printed and filmed instructions to the public, "cancer weeks," and the like. Dr S. REIMANN (Philadelphia) said that as a result of the educational campaign in the States there had been a steady decrease in the length of the period which elapsed before the sufferer sought medical advice. Sir JOHN ROBERTSON (Birmingham) spoke of the problem of the education of the public as it presented itself to a medical officer of health. Dr VEITCH CLARK (Manchester) made certain suggestions as to how the public mind could be cleared of some popular misconceptions regarding cancer, and Professor F. FICHERI and Dr L. M. McKILLIP described cancer campaigns respectively in Italy and in Australia.

DEMONSTRATIONS

On Tuesday afternoon visits were paid by the delegates to the Middlesex Hospital and the Radium Institute. In the Bland-Sutton Institute of Pathology, under the guidance of Professor J. McINTOSH and Drs BAKER, MORRIS, and PROGER, there were shown demonstrations of unusual tumours, studies of the Rous sarcoma, some experiments in lead therapy in cancer, and the application of the cinematograph to the study of tissue culture. At the Courtauld Institute of Biochemistry, Professor E. O. DODDS, Mr W. LAWSON, and Drs DICKENS and FRY WATSON had arranged demonstrations on the metabolism

of tumours, a trial of some unsuccessful methods for the sero-diagnosis of cancer, and routine observations on patients undergoing radical operation in the Barnato-Jool Laboratories, with Professor S. Russ and Drs. MORRISON and HELEN CHAMBERS in charge, there were demonstrations on the effects of x-rays and radium upon tumour growth, and experiments on the physiological action of x-rays. The delegates also witnessed operations in the theatres. At the Radium Institute demonstrations were given by Dr. PHILIP GOSSE and Dr. ROX WARD with radium applicators and radon "seeds," the preparation and filling of which were shown.

In the afternoon of July 18th a series of demonstrations was arranged at St. Bartholomew's Hospital to illustrate the value of the radiological treatment of cancer in various situations, the principles of the technique employed, and the pathology of the process. Mr. GIFFORD KRYNKA showed a series of cases of carcinoma of the breast treated, for the most part, solely by radium. In one or two of the earlier cases in the series this had been combined with surgical measures, but in the majority the application of radium alone had been found to be fully effective. The number of cases and the high degree of success rendered this demonstration one of exceptional interest. Mr. KEYNES later gave a practical demonstration of the insertion of radium needles for the treatment of this condition. Professor GASK showed a series of cases in which radon seeds had been employed for the treatment of rodent ulcer, secondary peritoneal growths, and cerebral tumours, the seeds being subsequently left *in situ*. In one instance the radon seed had been introduced into the pituitary fossa, the patient obtaining marked relief from giddiness, blindness, and headache, due to a tumour in this situation. Mr. FRANK ROSE, Dr. FINZI, and Dr. LEVITT exhibited several successful cases of treatment of carcinoma of the tongue and larynx, the contrast with the results of old methods such as laryngo-fissure being very striking. The value of deep x-ray therapy was also illustrated. Mr. ROSE also demonstrated the insertion of radon seeds in carcinoma of the oesophagus. Sir CHARLES GORDON-WARSON showed cases of carcinoma of the rectum treated by radium, and performed the operation for the insertion of radium in this condition. Gynaecological cases were shown by Drs. BARRIS, DONALDSON, and LEVITT, and the insertion of radium by the abdominal and vaginal routes for the treatment of uterine cancer was demonstrated in the operating theatres. A series of pathological demonstrations dealt particularly with tissue culture and the influence on mitosis of x-rays and radium. Dr. R. G. CANTI showed specimens illustrating the effect of radium on uterine cancer. Exhibits by Miss FELL and by other members from the Strangeways laboratories were also on view illustrating tissue differentiation *in vitro* of the ear, and of cartilage and bone, cultures of Jensen's rat sarcoma, and the delayed lethal effect of radium on tissues cultivated *in vitro*. Museum specimens of various unusual malignant tumours were also shown. Dr. CANTI later gave a cinematograph demonstration of living tissue cells cultivated *in vitro*, and indicated the action of radium upon them. It will be recalled that Dr. CANTI gave a similar demonstration at the Annual Meeting of the British Medical Association last year at Edinburgh, of which a report appeared in our columns on August 20th, 1927 (p. 313). Lastly, Professor HOPWOOD and Dr. LEVITT exhibited radiological apparatus, with special reference to deep x-ray therapy.

The visits paid by the delegates on Thursday afternoon were to the Cancer Hospital, Westminster Hospital, St. Mark's Hospital, and the Lister Institute. At the Cancer Hospital Professor Archibald Leitch was able to show the first Rous tumour produced by the ferment referred to in the discovery reported by Dr. Murphy of the Rockefeller Institute two days previously. Other demonstrations, experimental and clinical, were given, including one of animal tumours produced by various carcinogenic agents. The radiological department was the scene of further demonstrations, and operations for cancer were performed by the surgeons attached to the hospital. At the Westminster Hospital there were clinical demonstra-

tions by Mr. Stanford Cade and Mr. Arthur Evans, Dr. Branton Hicks and Dr. Hocking showed specimens, and the x-ray department was also open. At St. Mark's Hospital also operations were performed and demonstrations were given in the research and other departments by Dr. Cuthbert Dukes and others. At the Lister Institute there was a series of demonstrations by Dr. Thomas Lumsden, assisted by Miss Kohn Speyer.

On the last afternoon of the Conference demonstrations by Dr. W. J. Gye and Mr. J. B. Barnard were given at the laboratories of the Medical Research Council, and at Guy's Hospital demonstrations of crises and of deep-therapy methods were given by Dr. W. L. Watt, and in the theatre operations were carried out by the surgeons of the hospital. At the Royal College of Surgeons Dr. J. A. Murray gave a lecture on the Imperial Cancer Research Fund and its work, Sir Arthur Keith gave a demonstration in the museum, and other demonstrations of pathological specimens and of objects of historical medical interest were given by Mr. T. W. P. Lawrence and Mr. J. F. Thomson. The Wellcome Museum of Medical Science was open every day to the delegates, for whom some special exhibits were arranged.

On Saturday, July 21st, many of the delegates visited the Woolwich War Memorial Hospital on Shooter's Hill and inspected the operating theatres, wards, and special departments. This fine institution was erected as a memorial to the 6,240 residents of Woolwich who fell in the war, it was opened last November by the Duke of York, and descriptions of it appeared in our columns on May 14th, 1927 (p. 892), and November 12th (p. 886).

ETIOLOGY OF CANCER

The following note of his contribution to the discussion on this subject, reported in our last issue, has been received from Professor Blair Bell.

The title allotted to this discussion covers so wide a field of knowledge and of speculation that it is impossible for any speaker in the time at his disposal to do more than make a short general survey or to mention some one aspect of what in truth is a meshwork of interwoven and related chemical and physical phenomena. We may speak of predisposing factors of a constitutional nature, among which may be included inherited cellular characteristics, which can hardly be excluded from any pathological liability. We may identify metabolic changes in the acid-alkali balance, enzymic or co-enzymic modification in the blood, and even toxic states due to a variety of causes. We know, too, of many predisposing causes acting locally which have carcinogenic or precarcinogenic (precancerous) attributes, and for all we know these may be rendered more effective by association with constitutional predisposing factors. Coming to the question of the malignant neoplastic change itself, we are here on safer ground, for this aspect of the subject is more readily open to experimental attack and to pathological investigation. My own views concerning the nature of malignant neoplasia—namely, that it is a specific growth process of dedifferentiation back to the primitive type of cell represented by the chorionic epithelium—and the large body of evidence we have adduced in support of our thesis should be well known, for we have repeatedly discussed the matter in various publications. It may, however, with justice be argued that between the predisposing factor, whether it be sudden trauma or one of the long list of agents, extrinsic and intrinsic, that produce the precancerous state by what is called "chronic irritation," but which would be better described as gradual devitalization, possibly with reduction of the oxygen supply or diminution of the oxidation processes, and the ultimate degradation of the cell to an earlier phase of development, there is one event at least, possibly several, which determines the change-over from the highly specialized state to the reversionary retreat which enables the previously differentiated cell to survive. The questions I wish, therefore, to present are: (1) Is any intermediate factor apart from a metabolic change—for example, oxidation derangement—necessary? (2) If so, what is the nature of the intermediate factor? These are surely most difficult questions to answer on the evidence we possess. It is possible to believe that local, metabolic conditions which lead to the production of an excess of lactic acid, with the resulting aid to cellular multiplication and invasion, may be all that is necessary for us to postulate. On the other hand, if there be an intervening factor between cellular devitalization and malignant neoplasia, surely this ought—on *a priori* grounds—to be

related to the controlling factors of cellular differentiation which appear to be inherently connected with the relationship between one type of somatic cell and another adjacent type.

So it may be that metabolic isolation of a cell can be construed into a condition whereby there is a withdrawal or loss of the control of differentiation, or, indeed, it may be that the altered chemical state of the damaged cell may break some chemical relationship with and control by, adjacent cells. One can conceive all kinds of alterations in this direction as the result of changes in cellular permeability alone—a disturbance of co-ordinated intercellular equilibrium. In this connexion it is interesting to note that Fischer has observed that while the normal differentiated cell cannot survive alone—a single unit—in cultures *in vitro*, the neoplastic cell can not only do so, but also can multiply. It seems, however, that we are too far from a knowledge of these intimate physico-chemical matters—and the problem appears to be essentially a chemical one—to prosecute any method of attack on malignant disease along such vague lines. For the present it is important to recognize the factors concerned in cellular devitalization in order to institute preventive measures, and to understand the nature of the malignant process in order that we may conduct the treatment of the disease on scientific lines.

CORRECTION

MR VICTOR BONNEY asks that the following figures be substituted for those which appeared in the report of his remarks published in the *Journal* of July 21st (p. 106, col. 2).

Up to the end of 1927 he had performed Wertheim's operation 351 times. There were 53 deaths due to the operation—an operative mortality of 15.1 per cent. Of the 298 patients who survived the operation 139 had died of recurrence, and of the remaining 159, 13 had died of other diseases, of whom 6 survived over five years (3 survived over ten years), and 30 had been lost sight of, 17 after they had passed the five year limit (5 had passed the ten year limit), and there were 116 patients whom he was still in touch with. Of these latter, 64 had passed the five year limit, 35 of whom had passed the ten year limit, whilst the remaining 52 had been operated on at periods less than five years ago. In all then, 87 patients had survived the operation five or more years, 43 of whom had survived it ten or more years.

CANCER HOSPITAL DINNER

In connexion with the International Cancer Conference a dinner was given at the Langham Hotel on the evening of July 19th by the medical and surgical staff of the Cancer Hospital, London. The chair was taken by Mr W. ERNEST MILES, senior surgeon to the hospital, who had immediately beside him Sir John Bland Sutton (president of the Conference), Dr Rotgans (professor of surgery in the University of Amsterdam), Sir Berkeley Moynihan (President of the Royal College of Surgeons of England), Dr James Ewing (professor of pathology in Cornell University), Dr Raffaele Bastianelli (professor of surgery in the University of Rome), Professor C. Regaud (director of the Radium Institute, Paris), and Sir Richard Garton (secretary of the Conference). In submitting the toast of the "Cancer Hospital," Sir BERKELEY MOYNIHAN described the voluntary hospitals of this country as a monument to the compassion of the English people, and praised the work of the institution whose staff were the hosts on this occasion, recalling with special gratitude the memory of Charles Ryall. Two points he wished to drive home: that hospitals were not merely sanctuaries for the sick and suffering but also research institutions, and that research in ward and theatre must not be ranked behind that carried out in the "criminal investigation department" of the laboratory. The CHAIRMAN, after acknowledging the toast, proposed the health of the visitors from abroad, and expressed the debt of all present to the British Empire Cancer Campaign for providing an opportunity in this Conference of meeting workers from many countries and exchanging experience and ideas. As a surgeon it was now evident to him that henceforth surgery, when it attacked cancer, must work hand in hand with radium. The toast was responded to by Professor ROTGANS, who said that international co-operation offered the best hope for the conquest of cancer, and expressed on behalf of his fellow guests their warm appreciation of British friendliness and hospitality. Dr J. B. MURPHY (pathologist to the Rockefeller Institute, New York), who also spoke in reply, proclaimed his deep respect for British medical institutions, and in particular for the Cancer Free Hos-

pital, which, according to the minute book of 1851, was founded for "investigation and treatment," and the order of those words was significant. Further progress in cancer, he felt certain, must depend on consultation between surgeon, radiologist, and pathologist. The last toast, that of "The Chairman," was proposed by Sir CHARLES GORDON-WATSON, who paid tribute to Mr Miles's mastery of operative technique and his qualities as a sportsman and a friend.

England and Wales.

Centenary of a Yorkshire Medical Charity

THE hundredth annual meeting of the Medical Charitable Society for the West Riding of the County of York was held recently in Leeds, under the presidency of Dr A. G. Barrs, the minutes of the society record that it was established in 1828 "at a numerous and respectable meeting of physicians and surgeons of the West Riding of the County of York, held at Turnbull's Hotel, Leeds, on Friday, July 25th, Dr Thorp in the chair." In 1901 Mr Wheelhouse, who had at that time been treasurer for many years, wrote the story of its origin and of its early years, and showed how, with care, enthusiasm, and economy, the society had developed into its then flourishing condition. He concluded his preface with the triumphant sentence "Let the condition of the society, now in its seventy-third year, speak for itself, it is relieving thirty-four families, is distributing among them upwards of £1,200 every year, and, since it commenced its career, has disbursed among its applicants no less a sum than £34,403. Long may it succeed in carrying on so grand a work." He might have added that, at that date, the society held investments of the nominal value of £26,799. The hope expressed by Mr Wheelhouse has been more than realized, for during the twenty-seven years since it has distributed no less than £44,973 among its beneficiaries, making a grand total during the hundred years of its existence of £79,376, its invested funds have a nominal value of £44,996, in the purchase of which the sum of £40,604 has been expended. At the last annual meeting grants amounting to £1,874 were made for the year beginning July 1st, 1928, and, in celebration of the centenary, a bonus of about 25 per cent. of the grant to each applicant was given in addition. The society has thus undertaken to pay out in grants and in bonus for the current year the sum of £2,342, and the treasurer, Dr Wardrop Griffiths, was able to assure the meeting that it could do so without fear. The society is essentially a charity, for those who join do so from altruistic motives and no application made to the society has any legal claim to relief. It is not only a duty for everyone who is eligible to join the society, it is an act of wisdom, for if he himself, or those whom he leaves behind him, should require assistance, he will know that the necessities of the case will be considered by a body of his fellows, and that all that can be done in equity and in fairness will be done. Quoting again from Mr Wheelhouse's interesting pamphlet, we give the following extract from the report for 1895: "Of the former (a member, the last of whose family had passed away during the preceding year) it may be of interest to members to know that she and her mother and her father before them have been on our list of pensioners for no less than fifty-five years and have received in accumulated grants since 1840, when the first was made, no less a sum than £1,750! A handsome return for the four guineas, which was all that the father's membership had cost him—a fact which it seems to your officers should speak with trumpet tongue to non-subscribers." Candidates for membership have to be proposed and seconded by members to whom they are personally known and are elected at the annual meeting. The largest number of new members elected in any one year has hitherto been 63. This year, in celebration of the centenary, no fewer than 145 were elected, and the society now, for the first time, numbers more than 1,000, for the year begins with a membership of 1,043. Every medical man in the West Riding who is eligible for membership should consider joining this excellent society.

The Surrey County Sanatorium

In 1912 the Surrey County Council, under its tuberculosis scheme, began to arrange with hospitals and sanatoriums in London and elsewhere for the provision of beds for tuberculous patients, paying fees approved by the Minister of Health. At the present time about 400 patients are under such treatment. In 1913 the county council acquired a site at Milford with a view to possessing its own sanatorium. It was proposed to accommodate 200 patients at a capital cost of £35,000, or £175 per bed. In 1919 the cost was estimated at £80,000, or £400 per bed, and considerations of economy led to the postponement of the proposal to build the sanatorium. By 1924 the increasing number of patients requiring treatment led to 100 additional beds in existing institutions being occupied by Surrey patients. The original scheme for a sanatorium at Milford was extended with a view to accommodating 300 patients, amended plans were prepared, and the revised estimate became £198,000, or £660 per bed. The sanatorium is now complete, and has cost £210,000, or £700 per bed. There are six single story pavilions in the sanatorium, each containing 50 beds. Two pavilions are for patients in an advanced stage of the disease, four for intermediate and early cases. In the centre is the administrative block, with main-kitchens and dining rooms, connected with the pavilions by covered ways. The administrative block contains examination rooms, x-ray and dental departments, various offices, and residence for the assistant medical officers and the matron. The nursing staff is accommodated in a separate building. A water tower and a boiler-house form a prominent feature in the landscape. All water and heating pipes, electric cables, telephone wires, and fire mains are carried in a subway, to allow of easy examination and repair. The site of 110 acres cost £8,234. Building operations on the site began in April, 1926, the foundation stone was laid in May, 1927, and on July 20th of this year Mr Neville Chamberlain, the Minister of Health, attended to declare the sanatorium open. The chairman of the county council, after stating that there were more patients on the waiting lists in Surrey than could be provided with sanatorium treatment, emphasized the dual function of these institutions in providing direct benefit to individual patients and in removing potential sources of danger to others. The chairman of the public health committee said that, while in 1919 there were 3,000 known cases of tuberculosis in Surrey with 300 patients in various institutions, in 1927 there were 4,000 cases. The chief difficulty experienced was in finding beds for advanced cases. Mr Chamberlain, in declaring the sanatorium open, noted that while an appeal had been made recently in London for £100,000 for the prevention of tuberculosis, £200,000 had been spent in the single county of Surrey for the sanatorium treatment of the disease. Slowly but surely during the last fifty years tuberculosis was being mastered, and people were being led gradually to understand its cause and the way to reduce its incidence. The medical superintendent of a sanatorium had much to do in adapting circumstances to the condition of the patients, he must win their confidence and collaboration, and he would obtain the best results by devising occupations for those under his care. Sanatoriums were sometimes said to be a waste of money, but this statement was based on imperfect information. For their full success early diagnosis was important. Mr Chamberlain quoted evidence obtained from an investigation into the after-results in patients treated at the Brompton Hospital sanatorium, and concluded by urging the need for three procedures in dealing with tuberculosis: early diagnosis, careful conduct of institutions, and effective after-care work.

Light Treatment of Tuberculosis in Lancashire

A special report on the treatment of tuberculosis by artificial light has been prepared by Dr G. Lissant Cox, central tuberculosis officer to the Lancashire County Council, dealing with the methods adopted and results achieved in 1927 at the tuberculosis dispensaries in that county. Two experimental centres were established in 1925, and the satisfactory results of the treatment given to 187 patients in the following year determined the county council to undertake, with the approval of the Ministry of Health,

a comprehensive provision of facilities. This, when complete, will comprise fifteen light centres at tuberculosis dispensaries, and will involve the addition of one assistant tuberculosis officer and three tuberculosis health visitors. The council has also decided to pay the fares of necessitous patients attending the centres. There are now ten centres in full working order, seven, however, were opened this year or at the end of last year, so that the report deals only with three centres—Ashton-under-Lyne, Lancaster, and Chorley—which were in operation throughout 1927. Dr Lissant Cox states that in his experience the most suitable equipment of lamps is as follows: two long flame carbon arc lamps for general treatment, one mercury vapour lamp (Jiscenek or Hanovia) for general or local treatment, and one Kromayer water-cooled mercury vapour lamp for local treatment. It should be noted that the report does not suggest that other apparatus or methods are not equally satisfactory in producing results, the choice has been dictated partly by conditions incidental to dispensary work alone. The capital cost of the lamps and subsidiary equipment has varied from £135 at Preston to £550 at Ashton-under-Lyne, but the installations are not identical. At Lilles, where the dispensary has the standard equipment mentioned above, the capital cost is given as £210. In some cases, where the public electric supply is unsuitable, it has been necessary to install a motor generator to give the current required for the carbon arc lamps, a suitable generator costs about £100 but it is expected to repay its cost in a few years by the saving in current from the public supply. The treatment has been supervised by the consultant tuberculosis officers for the five dispensary areas into which the county is divided (there are also two small sub-areas supervised by the medical superintendents of sanatoriums situated within them), each dispensary area having, in addition, two assistant tuberculosis officers and from four to seven tuberculosis health visitors. At the three centres whose work is reviewed, patients have, as a rule, attended light sessions two or three times weekly, it has been found that patients who attended twice a week made, it seemed, as good progress as those who attended three times a week, but that the progress of those who attended only once a week was noticeably slower. About three fourths of the patients have been able to continue their normal occupations during treatment. Cases selected for treatment are chosen almost entirely from those suffering from non-pulmonary (surgical) tuberculosis, and who are able to attend the dispensary. The average duration of light treatment for those completing treatment in 1927 and becoming quiescent and apparently cured was 7.5 months, previously, these patients had been undergoing other forms of treatment for the much longer average period of 63 months. It is claimed by the report that the work in these three Lancashire centres has confirmed the view that great economy—and no less beneficial results—can be secured by light treatment of cases of non-pulmonary tuberculosis which would otherwise be sent to institutions for residential or out-patient treatment. Of the 110 cases concluding treatment in 1927 on attaining quiescence of diseases, the consultant tuberculosis officers would normally have recommended 44 for treatment at special or general hospitals, and 28 for out-patient treatment at a skin hospital. The estimated cost of such treatment, based on average duration, is not less than £1,436, while the actual cost (all inclusive) of their treatment at the dispensary light centres was £525, a saving of £911. Summarizing the results of treatment of cases of non-pulmonary tuberculosis Dr Lissant Cox states that they have been "very satisfactory," particularly in two conditions, (1) lupus, and (2) adenitis with abscess formation and skin involvement, both being usually refractory to other forms of treatment. Of the 70 cases of lupus treated at Ashton-under-Lyne (the two other centres had no suitable lamps for local treatment) during 1926 and 1927, 44 were discharged as quiescent and apparently cured, while of the 81 cases of adenitis treated at the three centres treatment was similarly concluded in 60 cases. Many of the lupus cases had been under other treatment previously for as long as twenty to forty years. The results of treatment of the other types of disease were often satisfactory.

but less striking. No permanent ill effect, either local or general, has been caused by artificial light treatment. The report, however, states

No general rule can be laid down as to how particular persons will react to the light as the response to the treatment varies within very wide limits. It cannot be too strongly emphasized that each patient must receive individual treatment and attention so far as initial exposure and graduation of exposure is concerned. Wherever possible a test exposure should be made before beginning treatment, in order to ascertain the sensitivity of the skin.

Of 106 cases which became quiescent and apparently cured in 1926, recurrences have occurred in three—one of lupus vulgaris, one of Bazin's disease and tuberculous adenitis, and one of adenitis.

Memorial to Mr Littlewood at Leeds General Infirmary

Twice during the year 1922—namely, on January 7th (p. 21) and again on May 27th (p. 844)—attention was called here to developments in the clinical teaching of medicine and surgery at the Leeds General Infirmary, and in referring to the appointment of the three full-time tutors it was pointed out that to secure the fullest advantage an effort was to be made to provide a properly equipped instructional block in the Infirmary and easy of access from the wards. In the near future this will be accomplished, for some time a completed portion of the new block has been in use, and the teaching staff can now visualize the realization of their desires at an early date. Particulars of the block and its equipment will be given at a later date when it is completed, but it may be mentioned now that the members of the honorary staff have subscribed a sum of money to carry out the equipment of the block and to place at its entrance a bronze relief of the late Mr Harry Littlewood, who died in December, 1921, as their double recognition of the valuable teaching work of a well-loved colleague. The bronze is the work of Mr G. L. Wyon, and shows Mr Littlewood in the service uniform of lieutenant-colonel R.A.M.C. At a pleasing ceremony held at the General Infirmary, which was attended by most of the members of the Board and Faculty and a few of Mr Littlewood's old friends, the bronze was unveiled by Mr H. Secker Walker, who was appointed to the honorary staff on the same day as Mr Littlewood. Mr Secker Walker gave a very interesting and sympathetic account of his former colleague's work and character and his outstanding qualities as surgeon and teacher. "With William Hey, Clifford Allbutt, Pridgin Teale, Fergusson McGill, Edward Ward, and others who have passed on, his name will rank high in the list of the most illustrious men who have spent their lives in the service of our General Infirmary." A vote of thanks to Mr Secker Walker was proposed by Mr Conpland and seconded by Mr A. L. Whitehead. In an obituary notice in the *Journal* of December 31st, 1921 (p. 1134), mention was made of the fine service rendered by Mr Littlewood to the Leeds Medical School, the General Infirmary, and the 2nd Northern General Hospital in that city.

Scotland.

Glasgow Chair of Physiology

THE retirement of Professor Diarmid Noel Paton from the chair of physiology in Glasgow University is announced to take effect from September 30th, 1928. The Secretary of State for Scotland has recommended the appointment of Edward Provan Cathcart, M.D., D.Sc., LL.D., F.R.S., to the vacancy. Professor Cathcart at present holds the chair of physiological chemistry in the University of Glasgow, to which he was appointed in 1919, and was previously professor of physiology at the London Hospital Medical School. He was born at Ayr in 1877, and graduated M.B. at Glasgow University in 1900, taking the degree of M.D. in 1904 and that of D.Sc. in 1906. He studied abroad at the universities of Munich, Berlin, and Petrograd, and was afterwards a research scholar at the Lister Institute in London. In 1905 he was appointed Grieve lecturer in chemical physiology

in the University of Glasgow, an appointment which he held till 1915, when he returned to London. He has made numerous contributions to physiological literature, especially on subjects dealing with physiological chemistry.

Edinburgh Medical Graduation

The summer graduation in medicine at Edinburgh University was held in the McEwan Hall on July 18th. Principal Sir J. Alfred Ewing presided, and conferred the degrees. At the close of the ceremony Professor Wright Smith, who acted as promoter, recommending the candidates for degrees, delivered the customary address, saying that he believed that at the present time the general average of attainment in medicine was higher than in past times. He recorded an anecdote of Robert Louis Stevenson which had been told to him by his predecessor in the chair of botany, Sir Isaac Bayley Balfour. Stevenson had, early in his career, taken the class of zoology at Edinburgh University, in this class he and Balfour had been posted together for the dissection of a complicated invertebrate—the crayfish. The work was divided on the principle that Balfour did the dissection while Stevenson read the details from the textbook. On the third day, however, under a summer sun, the crayfish had passed beyond dissection, and Stevenson departed never to reappear in the class. Thus experience, however, of the medical profession had given Stevenson a very high idea of medical men, and he had spoken of the doctor in the following terms: "Generosity he has, such as is possible to those who practise an art, never to those who drive a trade, discretion, tested by a hundred secrets, tact, tried in a thousand embassiments and, what are more important, Herculean cheerfulness and courage." The man in the street, Professor Wright Smith continued, had ideals about his fellow-men, even though he might not set a high standard for himself. The public therefore expected a high and inflexible standard from their profession. Medicine was no longer merely a healing art, for the trend of medicine was to be preventive. In the plant world it had long been realized that cure was at best difficult, and prevention was the aim. We were still far, perhaps, from the institution of a scientific medical police, and it was an important question whether the medical man was tending to be more and more of an official, for officials were not loved. The speaker believed, however, that as long as the ethical obligations so characteristic of the past continued on the same high level, the favourable status of the profession was assured. Opinions varied between expectations of rapid advancement of the human race and a pessimistic view that all the material improvements did not further in any way the moral and intellectual development of man. The triumph of the scientific world in the last fifty years had been chiefly in the physical field, but in this advance the medical man of the future would have his share, and the hope of the future was largely in the hands of present-day graduates. He advised his hearers to keep alive the spirit of inquiry which was open to all, for great workmen often worked with few tools. For a man to gain his due place in the scheme of things he required a calm courage, which came of confidence in self justly founded. In no profession was individuality more important than in medicine, not merely as a means of professional advancement, but in the everyday work of the physician. Great responsibilities often fell upon them which could not be shared with others. He advised them never to cease to believe in their great vocation, and so they would not lose their impetus.

Central Midwives Board for Scotland

At a special meeting of the Central Midwives Board for Scotland for the hearing of penal cases, Dr R. C. Burt in the chair, a certified midwife appeared in reply to a citation for contravention of the rules as to notification to the local authority of being in contact with a patient suffering from puerperal fever as also other breach of the rules. A health visitor gave evidence in support of the charges. The Board found the charges proved, and instructed the secretary to remove her name from the roll of midwives and to cancel her certificate, and in addition thereto, in terms of Section 8 of the Midwives (Scotland) Act, 1915, to prohibit her from attending women in childbirth in any other capacity.

Ireland.

Royal Victoria Hospital, Dublin

THE new wing of the Royal Victoria Eye and Ear Hospital, Dublin, which has been erected at a cost of £20,000 under the will of the late Mrs. Harvey Lewis, was declared open by the Governor-General of the Irish Free State at the annual meeting of the friends and supporters of the hospital, at which Sir George Roche presided. The meeting was largely attended. The Governor-General, in moving the adoption of the report, said that they would all agree that the accommodation provided by the new wing was greatly needed. The remarkable increase in the number of in-patients was sufficient proof of that, and it also proved that the work of the council and staff was appreciated throughout Ireland. He hoped that the establishment would meet with even more generous support in the future from all who sympathized with the prevention and cure of suffering. The chairman, in seconding the resolution, referred to the excellent work shown in the report, which, among other matters, mentioned that the number of visits paid in the out-patient branch exceeded 36,000. The medical men attached to the hospital had a world-wide reputation. Referring to the new wing, the chairman said that it had been erected at an expenditure of about £20,000, the fund coming from money left by the late Mrs. Harvey Lewis, in memory of her husband. By her will she left £80,000 for the building of a hospital in Dublin, to be called "The Harvey Lewis Hospital," but, in consequence of her death having occurred within three months of the making of her will, and as the greater part of her property consisted of real estate, only about £20,000 became available for the charitable purposes of the will, and that amount was allocated by the court for the completion of the hospital by the erection of the new wing. The judge held that the application of the fund in that direction was one that would most closely carry out the charitable intentions of the testatrix. The wing had only recently been handed over to the board by the builders, and was not yet furnished or equipped, it was, however, hoped that by the next annual meeting it would be in full working order. Dr. Winter, President of the Royal College of Physicians, moved a resolution declaring that the hospital was worthy of public support. He said that it was the only hospital in the Free State devoted altogether to eye and ear work. There was a constant pressure of applications for beds, and he hoped that the new wing would enable them to cope with that trouble.

Bequests to Belfast Hospitals

The late Mr. Frederick L. Heyn of Belfast, who died in February leaving estate valued for probate at £209,707, has bequeathed £1,000 to the Royal Victoria Hospital, Belfast, to name two beds, one to be called the Frederick L. Heyn and Helen B. Heyn bed, and the other the F. L. Heyn Head Line of Steamers bed. Among his other bequests are £250 each to the Belfast Maternity Hospital and the Society for Providing Nurses for the Sick Poor of Belfast, £200 to the Samaritan Hospital, Belfast, and £100 to the Belfast Hospital for Sick Children.

The Free State Dentists Bill

In the Report stage of the Dentists Bill the Seanad accepted a Government amendment to add a section dealing with the position of any person who before the establishment of the board satisfied the responsible Minister, or after the establishment satisfied the board, that he fulfilled certain conditions, namely, that he was a citizen of the Saorstát on January 1st, 1928, that he was on December 31st, 1921, not less than 21 years of age, that his principal means of livelihood during the whole period of seven years immediately preceding the passing of this Act was the practice of dentistry in the Saorstát, and that he was not guilty at any time of any crime or conduct which, if he had at that time been a registered dentist, would have caused his removal from the register. Every person to whom the section applies shall, on passing either of the examinations in dentistry to be prescribed and held

under this section, and on making the prescribed application, and paying the prescribed fees, be entitled to be registered. Two examinations will be held under this section, the first approximately five months, and the second approximately eleven months, from the passing of the Act.

Local Authorities (Officers and Employees) Bill

The Local Authorities (Officers and Employees) Bill, introduced by Mr. L. De Valera, was defeated in the Dáil on the second reading by 76 to 47 votes. The Labour Party voted in the majority, with the Government, against the bill.

Correspondence.

HOLIDAYS FOR ORPHANS OF MEDICAL MEN

In Typeal

SIR,—The applications for assistance from the Royal Medical Benevolent Fund have in recent months been exceptionally numerous and urgent, and further subscriptions and donations will be gratefully received at 11, Chandos Street, Cavendish Square, London, W. 1.

A special plea which appears at this time of the year is for help for children. In co-operation with our Ladies' Guild and other bodies the committee of this Fund is often able to secure admission of children of deceased medical practitioners to orphanages or schools where free education is given.

During the holidays provision must be made for these children, and when there are no friends or no friends in a position to receive them, the difficulty is great. The committee does what is possible, but their efforts are much hampered by the lack of funds—I am, etc.,

THOMAS BARLOW,
President

11 Chandos Street W. 1 July 23rd

TROPICAL AUSTRALIA

SIR,—Criticism of the views expressed by me on the problem of the colonization of tropical Australia by a white race continue to appear. Dr. J. F. C. Haslam, in addressing the Section of Tropical Diseases and Parasitology, as reported in the *Proceedings* of the Royal Society of Medicine for April 1928, made allusion to life assurance in the tropics, and expressed doubt respecting the conclusion reached by me. A communication was at once addressed to three of the leading life assurance companies in Melbourne, with the following result: The Australian Mutual Provident Society, Australian Temperance and General Mutual Life Assurance Company, and the National Mutual Life Assurance Co., Ltd., impose no loading whatsoever on proponents for insurance by reason of their residence in tropical Australia. All of them impose loading of varying degree, according to circumstances, on those who intend to reside in Papua or the Australian mandated territories, all of which are islands separated from the continent.

Any reference to the official reports furnished by the Commonwealth Government respecting the mandated territories will show that there is good reason for loading in these cases. These islands contain a large native population heavily infected with some, but not with all, tropical diseases. The hygienic conditions in these extensive regions are in striking contrast to those in tropical Australia. The climates are not dissimilar, but in Australia there is practically no infected native population. My own opinion is that if Australia did contain such a population the health conditions would be similar to those met with in other tropical countries.

Criticisms of the view expressed will, no doubt, continue to appear, and I shall try and answer them to the best of my ability. May I, however, again state that the conclusion reached has nothing to do with political considerations, it is based solely on the facts referred to in the vital statistics of tropical Australia, and on my personal experience of tropical Australia and of other tropical countries—I am, etc.,

Melbourne June 15th.

JAMES W. BARRETT

THE PAPILLAE FOLIATAE AND CARCINOPHOBIA

SIR,—In your issue of July 7th (p 13) Mr C Jennings Marshall, in the memorandum "The papillae foliatae and carcinophobia," gives some interesting information. I have recently had three such cases, all of which occurred in women at the menopause, and all of which were bilateral.

Mr Marshall divides them into two types—namely (1) where the papillae are in no way diseased but cause grave worry to the physically introspective patient, (2) where the papillae are oedematous and swollen, and cause pain. The latter he attributes to infection from an adjacent tooth or tonsillar crypt.

In the most recent and pathologically affected of my cases I have been quite unable to find any site of infection. When the patient came to me all her teeth had been extracted many months previously, and she had been under treatment elsewhere for a "painful tongue" for nearly a year. On examination I found the papillae reddened, swollen, and painful, and the carcinophobia was so marked as to produce persistent insomnia. I emphatically assured her that she had no cancer. The result was spectacular. Not only did her general condition immediately improve, but the papillae themselves rapidly returned to the normal non-pathological state.

The patient gratefully attributes the rapid cure to the magical properties possessed by the "bottle." In reality the magic was contained in the statement (which Mr Jennings Marshall claims to be the sole duty of the medical practitioner), "You have no cancer"—I am, etc.,

M INNES FRANKELL, M B, Ch B

Castleford, July 14th.

GASTRIC SECRETION OF NEUTRAL CHLORIDE

SIR—Dr E P Poulton, in his letter of April 28th (p 729), says the papers of Hansman, Dav, and Clifton, and of Campbell, Baird, and Hern, had evidently been missed by Professor Hugh MacLean in his review of the literature. A copy of the *Australian Medical Journal* and a reprint containing the article were posted to Professor MacLean in July, 1927, and I have verbal and written proof that the paper was read and discussed by members of the Medical Unit of St Thomas's Hospital, therefore the failure of Professor MacLean and his colleagues to refer to our article in their papers in the *Journal of Physiology* of March 30th, 1928, in which essentially the same conclusions are drawn as expressed by us, needs some other explanation. I felt this oversight to give the usual recognition of priority somewhat keenly, as I worked in the Medical Unit of St Thomas's Hospital for nearly two years, but up to the time I left, over four years ago, there had been no mention of any proposed work on gastric chlorides, nor did I know that any such work was in progress till after our article was published—I am, etc.,

Sydney New South Wales June 17th

F S HANSMAN

IMMUNIZATION IN SCHOOLS

SIR,—In the latest issue of the *Journal* to hand (May 19th, p 881) I note that the medical officer of a well-known public school has successfully brought a civil suit against a parent who was dissatisfied with the treatment meted out to his son who sickened of scarlet fever during term. In our small community at Hankow we have followed the instructions of the medical officer of health for Aberdeen (Dr Kinloch) and have immunized most of the white children against diphtheria and scarlet fever—using the products of Messrs Mulford, Lilly, and Parke Davis. Possibly by the time I see England again there may be an extension of the Public Health Act, whereby will be facilitated the prosecution of parents who send non-immunized and susceptible children to a public school, causing unnecessary danger and expense by spreading preventable diseases. The school in question has apparently no rule barring the admission of boys susceptible to these diseases. When will one of the larger public schools take a lead in this matter?—I am, etc.,

Hankow June 29th.

A H SKINNER

THE OPTICIAN AND THE MEDICAL PROFESSION

SIR,—A few months ago a schoolmistress brought a child to me and asked if I would prescribe the necessary drug to dilate the child's eyes, as she was taking it to an optician in London to have spectacles fitted. I explained to her what "covering" meant, and my inability to prescribe the drug. In the meanwhile she had apparently communicated with the optician again, and wrote me a letter requesting that I should do what was necessary, at the same time enclosing a letter from the optician. The latter in his letter to her stated "Most doctors know the drug required to dilate the eyes of a child, as for myself I am not allowed to write the simplest prescription." It would be interesting to know if opticians make a practice of asking their customers to prevail upon doctors to prescribe mydriatics for their benefit—I am, etc.,

Haddenham Bucks July 10th

T W S PATERSON

THE PROBLEM OF CANCER

SIR,—In his address on this subject, printed in your issue of July 7th (p 1), Sir Lenthal Cheate concludes by saying "The answer to this question can be only, that the problem will never be solved completely until we know what life is."

One thing we do know—it is that the continuance of life and growth are due to fermentative activity, and it is very probable that a disturbance of the chemical reactions brought about by ferments is responsible for irregular growth. Nor should we lose sight of the fact that evolutionary processes are going on all the time. According to Ehrlich and others chemical evolution proceeds apace. New ferments are being formed even at the present time to deal with new conditions, and structure and arrangements are modified accordingly.

I sometimes wonder, indeed, if cancer is not an attempt—so far a ghastly one—at the production of a new gland, for several observers have found evidence of enzymic activity in malignant cells—I am, etc.,

Upholland nr Wigan July 10th.

J THOMSON SHIRLAFF

BATTERSEA (ANTIVIVISECTION) HOSPITAL

SIR,—It has been brought to the notice of the Research Defence Society that the action of Mr J F Peart, F.R.C.S., in addressing the annual general meeting of the society on June 19th is being construed in certain quarters as if he had been called up by the society to explain his conduct while at the Antivivisection Hospital at Battersea. May I be permitted to state that Mr Peart's action was entirely voluntary and made in the interests of the public—I am, etc.,

G P CROWDEN,

Honorary Secretary Research Defence Society

Obituary

WE regret to record the death of Dr GEORGE BALSILLIE of Kendal on July 1st, after a short illness, at the early age of 37. He received his medical education at the University of Edinburgh, graduating M B, Ch B in 1917, and entered the Royal Navy, in which he held a commission as surgeon lieutenant until 1920. After serving for the usual period as house-surgeon to Sir David Wallace in the Edinburgh Royal Infirmary, he commenced general practice in Kendal, and soon took an active interest in professional affairs. Two years ago he was elected honorary secretary of the Kendal Division of the British Medical Association, and at the time of his death he had been appointed a member of the Representative Body. Dr Balsillie was, further, secretary to the Westmorland Cancer Commission and anaesthetist to the Westmorland County Hospital. He was a past-president of the Kendal Rotary Club and a Freemason, and as a member of the St John's Presbyterian Church Kendal served as an elder and as session clerk. A colleague writes "His death removes a public spirited, conscientious, and capable practitioner who will be greatly missed."

¹ Mansell Moulin *Biology of Tumours*.

Dr WILLIAM KICKHAM HEFFERNAN, who died at Killennule, co. Tipperary, on July 15th, in his seventy-sixth year, was the son of Patrick Heffernan of Cuckoo Hill, Cahu, whose patronymic is an anglicized form of an old Gache name, and Catherine Kickham, of Knockelly Castle, Felthard, whose ancestors settled in Ireland under Cromwell's regime. That they were speedily absorbed is shown by the fact that one of the family Charles Kickham, the novelist and poet narrowly escaped execution as a Fenian rebel in 1867. Dr Heffernan who was thus a typical example of the mixture of races which has produced the "men of Tipperary" was educated at Clongowes Wood College, proceeding thence to his professional studies at the Catholic University, Dublin. He obtained the diplomas L.R.C.P.I., L.R.C.S.I. in 1874, and was subsequently appointed to a resident post in the Mater Misericordiae Hospital, Dublin. Later he spent some years at Jarrow-on-Tyne before returning to commence practice in the county of his birth, where he was for a period medical officer of health for Killennule. Dr Heffernan held office as a justice of the peace for the county, and was for long a well-known member of the Tipperary Hunt. He is survived by his widow, one son, and one daughter. One of his sons was killed during the war while serving as an officer in France.

We regret to announce the death of Dr. FRANK STORRY MOLYNEUX of Leamington which occurred on July 16th as the result of septic poisoning contracted in the performance of an operation in a case of gas gangrene at the Wanstead Hospital to which he gave his services as honorary surgeon. He was the eldest son of the Rev. F. F. Molyneux, rector of Marton, Worthy, and was born in 1880. He received his medical education at the London Hospital, where, after obtaining the diplomas M.R.C.S. and L.R.C.P. in 1905, he subsequently became assistant demonstrator in physiology and clinical assistant in the aural and skin departments. He was afterwards senior house-surgeon for a period at the Royal Surrey Hospital, Guildford. During the war he held a commission as captain in the Royal Army Medical Corps, serving as a surgical specialist at Bourne-mouth and with a casualty clearing station in France. He was also, at one time, honorary surgeon to the British War Hospital, Wimborne. Dr. Molyneux was a well-known personality in the medical profession in the Midlands, where he was held in high esteem as a surgeon and radiologist. He took a keen interest in professional affairs, he was a Fellow of the Royal Society of Medicine, a member of the British Medical Association, and of the Leamington Medical Society, and the author of a number of contributions to medical journals, mainly on the use of radium. His chosen sport was fox hunting, and he was widely known as a keen and straight rider to hounds. His funeral, which was attended by a large number of his medical colleagues, was led by his favourite hunter, saddled and bearing his pink coat and top-boots.

The Services

INDIAN CANDIDATES FOR THE I.M.S.

Certificates of Age and Nationality

NEW rules governing the issue of certificates of age and nationality to natives of India who are candidates for permanent appointment to the Indian Medical Service have been published by the Government of India in an army department notification (No. 864), dated June 16th.

It is provided that certificates will require the signature of the secretary to the Government of a province, the commissioner of a division or the highest political officer of an Indian State, according to the area in which the family of a candidate resides, and it is to one or other of these officials that a candidate should, in the first instance apply, stating his desire to obtain a commission in the Indian Medical Service. An inquiry will then be made by the magistrate of the district or political officer of the State in which the applicant's family resides. These officers will interview candidates and other relevant witnesses regarding date and place of birth and will scrutinize any documentary evidence available such as horoscopes, family books, tradesmen's account books showing entries relating to births, school records, and matriculation records. A full report of the inquiry with copies of documents etc., comments and an expression of opinion will

be forwarded by the officer making it to the officer to whom the application was in the first instance addressed.

It is provided that a duly certified extract from a register kept by a public official in British India will, where available, be accepted as sufficient proof of the date and place of birth. After the application of the new rules any declaration of age recorded in a formal and deliberate manner will be taken as conclusive evidence in disproof of the subsequent assertion by the same person that he is of a different age.

Where the evidence produced by a candidate who is a British subject is satisfactory the competent official (secretary to a Government commissioner of a division or highest political officer in a native State) will issue the required certificate of birth and nationality. If the evidence is not satisfactory the certificate will be refused and the candidate will be unable to obtain admission to the Indian Medical Service. Where a candidate who is a subject of an Indian State satisfies the authorities regarding the date and place of his birth and his nationality the papers with any bearing upon the nationality of his father, will be forwarded to the Government of India who will consider whether a declaration of eligibility shall be issued.

A certificate may be granted to the father or guardian of a candidate who has proceeded to England provided that satisfactory evidence is produced, and that it is stated when the candidate went to England and where he has resided during his stay in that country. In the case of a Tamil or Ceylon the production of a certificate of age and nationality, signed by the secretary to the Government of Ceylon and similar to that demanded from natives of India will be required. This certificate must show that evidence has been given that the candidate is the son or grand-son of a person born in British India.

Medico-Legal.

RECKLESS CHARGES OF NEGLIGENCE

THE Eastbourne County Court judge's comments sufficiently describe the reckless allegations of negligence recently brought by Mrs. Grace Edith Hunt against Dr. Elfrida Coghill, medical attendant at the Eastbourne Corporation Maternity Home. The matters complained of occurred four years ago, but Dr. Coghill waived her right to plead the Statute of Limitations because she naturally desired that the full facts should be investigated by the court. The plaintiff was a patient of Dr. R. R. Pirrie, who sent her to the home in March 1924, suffering from albuminuria of pregnancy. She was attended by Dr. Coghill, but her condition being grave, Dr. Pirrie was called in, and after a consultation, he induced labour, a seven months child being born. Diet was the principal treatment, there being danger of eclampsia, and the plaintiff's life was saved. The child, however, died. It was stated, in evidence, that the plaintiff was below the normal, both physically and mentally. Both doctors agreed that, but for the treatment they gave, the plaintiff herself would have died, it being a question of whose life should be saved—the mother's or the child's. His Honour Judge Cunniff, in dismissing the action, praised the skill shown by the medical attendants. It became a question of saving either the life of the mother or possibly the life of her unborn baby, which would undoubtedly have been a puny weakling. The doctors, in the exercise of their discretion, most properly decided to save the life of the mother, and save it they did. The result of their exercising that discretion in saving the plaintiff's life had been that the most reckless charges had been brought which ought never to have been dreamed of. His Honour added that it was hardly necessary to say that the whole public had been grateful for the way in which the Maternity Home had been carried on and for the services rendered to the people who had occasion to use it.

BOGUS DOCTOR SENTENCED FOR FRAUD

A nature cure practitioner William Patrick Faulkner whose previous occupation was stated to have been that of a carpenter, was found guilty at Marylebone Police Court before Mr. Bingley, on July 16th of obtaining two sums of money by false pretences from Ernest Rose, another carpenter with intent to defraud and was sentenced to three months' hard labour on each charge—six months in all.

It was alleged at a previous hearing that the two men entered into partnership in premises at Praed Street, Paddington in a "Nature cure establishment and sunray clinic," Rose stating that Faulkner claimed to have qualified as a doctor of medicine at King's College, London. Mr. Wallace, for the Director of Public Prosecutions said that the charges against Faulkner related to £4 which he was alleged to have obtained from Rose to enable him to register his name with the General Medical Council and to £8 8s. which Faulkner said he wanted for registering the premises with the London County Council. The prosecutor stated that the accused signed the partnership agreement as William Patrick Faulkner M.D. and that a brass door plate on the Praed Street premises was inscribed "Doctors Faulkner and Rose Nature-Cure Practitioners and Manipulative Surgeons."

Evidence was given that the clinic was open for eight weeks or so and that about ten people were treated by according to Rose Faulkner. Rose answering Mr. Bingley stated that hardly any of the persons treated paid. It was disclosed in the course

of the second day's hearing, that Faulkner had, on a previous occasion, been fined £20 and ordered to pay ten guineas costs for falsely describing himself as a registered medical practitioner. The accused, giving evidence said that he was a member of the "Natuero Curo Practitioners Association."

Mr Wallace remarked upon the danger of sun ray treatment by unqualified people: one patient he said who paid the prisoner £6 and was treated on two or three or more occasions, was finally sent to hospital and found to be suffering from appendicitis. If she had gone on attending the clinic much longer he added she would probably have ceased to require any treatment at all.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

IN the House of Commons this week the Finance Bill, the Companies Bill, and the Registration (Births, Deaths, and Marriages) Bill were read a third time, and unemployment, particularly in the mining industry, was discussed. A vote of censure moved against the Government on this subject by the Labour party was defeated. The House of Lords advanced a number of Government bills, including the Reorganization of Offices (Scotland) Bill, which passed through Committee, the Food and Drugs (Adulteration) Bill and the Shops (Hours of Closing) Bill, which were read a third time and passed, the Marriage (Prohibited Degrees of Relationship) Bill, which amends the law relating to the marriage of persons with a nephew or niece by marriage, was read a second time, as also was the Rating and Valuation (Apportionment) Bill. With regard to the last named bill Earl BEAUCHAMPEL regretted that the measure proposed no relief to hospitals.

Finance Bill Allowance for Earned Incomes

During the Report stage of the Finance Bill in the House of Commons on July 23rd Mr LEE-SMITH moved a new clause providing that the allowance for earned incomes should be increased from one-sixth to one-fifth. Mr GILBERT in seconding the new clause said a man who had qualified as a doctor might have been given very little beyond that qualification by his father and might have little capital. A man in private practice making his £1,000 a year might have hardly any capital. A larger allowance in respect to income tax should be made to such a man than to a man in a similar position who drew his income from investments or accumulated wealth which he might have inherited. Mr A. M. SALUZZI said that although the Chancellor of the Exchequer would like to grant the concession he was not in a position to do so. It would cost £2,100,000 a year and they could not spare the money. The new clause was rejected by 240 votes to 114.

Scientific Cinematograph Films Exemption from Duty

On the Report stage of the Finance Bill in the House of Commons on July 23rd Captain FRASER moved a new clause providing that the Customs duties imposed on negative and positive cinematograph films should cease to be payable in the case of a film certified by the Royal Society of London to be solely an illustration of scientific investigation for exhibition before members of a recognized scientific body and imported only for the purpose of such exhibition free of charge. Captain Fraser said that great developments had taken place in the technique of the use of films as a record and illustration of scientific research. He was happy to say that by the instructions of the Chancellor of the Exchequer conversations had taken place with the Customs officials which led him (Captain Fraser) to suppose that this clause could be worked by them if the House wished to pass it. The Royal Society would undertake the liability which it suggested it should be asked to undertake.

Mr CHAMBERLAIN in seconding said that such a concession would give a tremendous stimulus to the preparation of scientific films for use in medical and surgical cases.

Mr A. M. SALUZZI was glad to say that he could now accept the clause. The Royal Society of London would certify when required that a film was an illustration of scientific investigation. That was a statement which the Customs officials could accept. He did not think that the loss to the revenue would be more than £200.

The clause was read a second time and added to the bill.

Infectious Diseases Notified in 1927-28.—Sir KINGSLEY WOOD on July 23rd, told Mr LANSBURY that during the fifty two weeks ended June 30th last the cases of small pox and other infectious diseases notified in England and Wales were as follows: Small pox 13,526 cases; scarlet fever 93,206; diphtheria 60,668; enteric fever 3,667; pneumonia 60,303; puerperal fever 2,238; puerperal pyrexia 5,366; cerebro-spinal fever 408; acute poliomyelitis 749; acute polio-encephalitis 104; acute encephalitis lethargica 1,452; typhus fever 3; continued fever 24; dysentery 673; ophthalmia neonatorum 5,492; erysipelas 15,736. The figures for tuberculosis were not given as so many corrections were received to the weekly figures that the totals were not made up until after the end of the year. The figures include port sanitary districts but not cases among non-civilians.

Deaths from Lysol Poisoning.—Answering Sir Frank MEYER on July 18th Sir W. JOYNSON HICKS said there had been a considerable increase during recent years in the number of deaths from the taking of lysol. The Home Office had brought the relevant

statistics to the notice of the Inter Departmental Committee now considering the law relating to the sale of poisons. The provisional figures for deaths from lysol poisoning in 1927 were—by accident 15, by suicide 361.

Allonal.—In a reply to Mr Robert YOUNG on July 19th, Sir W. JOYNSON HICKS said the Dangerous Drugs Act did not apply to "allonal" which was the proprietary name given by a Swiss firm of manufacturing chemists to a derivative of barbituric acid. He was aware of the dangers entailed in its use, and had brought the question of the need of further restrictions before the Inter Departmental Committee.

Administration of the Lunacy Acts.—Mr CHAMBERLAIN told Mr PETHICK LAWRENCE on July 19th that he had arranged for the administrative recommendations of the Royal Commission on Lunacy to be borne constantly in mind in the day to day administration of the Lunacy Acts. These recommendations were followed so far as was practicable. The problem of the after-effects of encephalitis lethargica was under constant review. Under the Mental Deficiency Act passed last year it would be possible to deal with certain of the patients suffering from the effects of that disease who were not suitable either for lunatic asylums or Poor Law institutions.

Deaths from Puerperal Causes.—Sir W. JOYNSON HICKS informed Mr VIANI on July 19th that he had no power to make an order that an inquiry should be held in all cases where death had resulted from puerperal causes. The Minister of Health was arranging with the concurrence of the British Medical Association for maternal deaths to be investigated for scientific and public health purposes by competent medical officers in each area. These investigations would be considered by the Committee on Maternal Mortality which Mr Chamberlain had recently appointed.

Foot and Mouth Disease.—Mr GUINNESS has brought before the Foot and Mouth Disease Research Committee the suggestion of experiments in the feeding of pigs upon remnants of Argentine meat to determine the risk of infection with foot and mouth disease from this imported meat. Mr Guinness states that while foot and mouth disease still prevails in Western Europe he is not prepared to withdraw the prohibition against the import of fresh meat from the Continent.

Voluntary Insurance.—Mr Chamberlain told Major CARVER that the possibility of widening the scope of voluntary insurance under the joint scheme of national health insurance and contributory pensions was still under consideration, but he had not yet found a satisfactory solution of the serious difficulties which any such proposal presented.

War Pensioners in Mental Institutions.—At the end of June 6,292 patients in mental institutions were maintained by the Pensions Ministry, their disabilities being due to war service. Exchequer grants are made for the maintenance in mental institutions of rather over 500 ex-service men whose condition was not due to war service.

Vaccination and Nervous Diseases.—Mr CHAMBERLAIN answering Mr RHYA DAVIES on July 19th said the report of the Committee on Vaccination would deal with cases reported to that Committee while in session where encephalitis and other diseases of the central nervous system had occurred within a short period after vaccination. The Ministry of Health had arranged to investigate similar cases which were brought to their notice.

River Pollution by Artificial Silk Works.—Sir KINGSLEY WOOD stated on July 24th that the Minister of Health was aware of the pollution of the River Gipping caused by the effluent from the artificial silk works at Stowmarket. He had no confirmation of cases of illness or of poisoning of stock from pollution but had received from the rural district council an application for consent to take proceedings against the company and had directed a public inquiry to be held.

Illness due to Antimony Compounds in Lemonade.—On July 24th Mr W. THORNTON asked the Minister of Health if his attention had been called to a report by the Newcastle city analyst about the illness of at least fifty of the staff of one of the big shops in the city caused by antimony compounds contained in the lemonade which the assistants drank if he was aware that the cause of the illness was in consequence of the enamel on the buckets which contained the made up lemonade and whether he intended taking any action in the matter. Sir KINGSLEY WOOD replied that the attention of the Minister of Health had been drawn to this case, and he understood that the facts were as stated in the question. The city medical officer of health was preparing a report on the occurrence on receipt of which the Minister would consider what action if any could be taken.

Notes in Brief

Mr Chamberlain announces that the inquiry into the projected erection of a tuberculosis centre at the Denmark Road corner of Oxford Road Manchester will be held before a medical officer and an architect on the staff of the Ministry of Health.

There were 16,522 cows and heifers slaughtered in 1926 under the Tuberculosis Order (1925) and 16,708 in 1927. Mr Guinness is satisfied that the Order is properly executed.

The Geneva Protocol of 1925 prohibiting the use of poison gas in warfare has only been ratified by six States. The British Government is not prepared to ratify unless all the other signatories are ready to do the same.

A firm in the West of Scotland recently used imported inedible hog grease after refining in the manufacture of hog lard. The stocks are under the embargo of the public health authorities and the Scottish Board of Health is considering the question of legal proceedings.

the College
Dr G D T Kerr Cross (Natal) Dr R H H Newton (Edinburgh) Dr Thomas Telfer (Dunbarton) Major B H H Neven Spence R.A.M.C and Dr R D Macleuzie (Edinburgh) were elected Fellows of the College

It was announced that Dr Robert Dods Brown had been appointed Morrison Lecturer for 1929.

At an extraordinary meeting of the College held the same day it was decided to confer the honorary Membership of the College upon Dr John Stewart Muir (Selkirk).

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh, held on July 19th when Mr Alexander Miles (President) was in the chair the following 26 successful candidates out of 81 entered who passed the requisite examinations between March 25th and 31st were admitted fellows:

W R. Angus G I. Boyd, H C. Carter H S. Chhabhi R O. Davidson N J. Everard E S. Freshman F C. Hunt S. Hunter C S. James L. A. Jamieson R O. Jones J. Kemrey A. V. Kishorebitha A. Leish R G. Mallory W G. Maclean L. H. MacGillivray C M. Plimpre G F J. A. Robinson L. Ross A. J. Stoot, it being W R. C. Stowe Beatrice L. Turner R. Watson.

The Iverson MacAdam Memorial Prize, consisting of bronze medal and set of books has after a competitive examination in organic chemistry, been awarded to Mr M. Goldfar.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY—E. L. Clarke E. G. Millard H. Tenebano;
MEDICINE—M. K. Bryce J. P. Collinson N. Des W. B. Halloms A. H. Henessey L. P. Johnson E. A. Lipkin H. S. Marks;
FORENSIC MEDICINE—T. A. Barnabas P. C. Bean H. C. Clifford Smith J. P. Collinson H. H. Jackson E. P. Johnson A. A. Leibovitch T. A. P. Proctor H. Tenenbaum;
MIDWIFERY—T. A. Barnabas P. C. Bean J. R. Bray A. R. D. Abren H. W. E. Drake N. H. Kettlewell S. M. Mahman.

The diploma of the Society has been granted to Messrs P. C. Bean M. K. Bryce K. F. Clarke W. B. Halloms and H. S. Marks.

Medical News.

THE Medical Research Council announces that on behalf of the Rockefeller Foundation it has awarded two fellowships provided by the Foundation and tenable in the United States of America during the academic year 1928-29. The recipients are Mr L. E. Bayliss, Ph.D. Cantab, Sharpey Scholar, University College London Dr A. V. Neale, resident medical officer, Children's Hospital, Birmingham, Mr F. J. Worsley Roughton, Ph.D. Cantab lecturer in physico-chemical aspects of physiology, University of Cambridge, Dr Dorothy S. Russell, research worker in the Baron Institute of Pathology, London Hospital and Mr A. Wormald, M.Sc. Leeds, lecturer in biochemistry, University of Leeds. These fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine or surgery, and who are likely to profit by a period of work at a university or other chosen centre in America before taking up positions for higher teaching or research in the British Isles.

THE Fellowship of Medicine and Post Graduate Medical Association announces that a special course in diseases of the chest will begin on Monday, July 30th for one week at the Brompton Hospital. From August 6th to September 1st clinical and cystoscopic demonstrations will be given by the staff at the All Saints Hospital on Mondays, Wednesdays, Thursdays, and Saturdays, those enrolling should apply to the hospital for particulars as to the times of operations. There will be a two weeks course, under Dr Pritchard's direction at the Infants Hospital from August 13th to 25th visits will be made to other baby welfare centres. The staff at St Mary's Hospital will undertake an all day "refresher" course from August 27th to September 8th, consisting of demonstrations in all departments of medicine, surgery, and the specialties. Copies of syllabuses and information regarding the general course of the Fellowship may be obtained on application to the Secretary, 1 Wimpole Street, W.1.

At a meeting of the Central Midwives Board for England and Wales on July 12th a letter from the Ministry of Health was read announcing the Minister's approval of the new rules for a period of eighteen months from June 30th last. Matters dealt with by the Standing Committee included a letter from the Departmental Committee on the Training and Supply of Midwives inviting the Board to give evidence before the committee, and asking whether the Board would be in a position to arrange for its representatives to give evidence early in October. It was agreed that the secretary be instructed to give evidence on behalf of the Board, and that the memorandum of his evidence be approved by the chairman of the Board. Sharon Green Maternity Home, Preston, was approved as a training school, and, subject to conditions, approval was also granted to Bramley Infirmary, Leeds. Approval as lecturer was granted to Dr Annie Beattie.

THE tenth annual meeting of the Mental Hospitals Association was held at the Guildhall, London on July 18th, with Sir William Hodgson, who was re-elected chairman for a further term, presiding. A resolution was carried urging the Minister of Health to introduce in the present Parliament a bill dealing with the pressing matters arising out of the Report of the Royal Commission on Lunacy and Mental Disorder. Reference was made to the inadequacy of the existing accommodation in mental hospitals, and to the fact that there is little or no room for the large class of inpatient cases, which were still untreated except to a limited extent. It was stated that without additional parliamentary powers little could be done. Several speakers called attention to the problems arising from the after-effects of encephalitis lethargica, reference being made to the recent Ministry of Health report on this subject, which was discussed in these columns on June 30th (p. 1125). The opinion was expressed by several speakers that few cases of encephalitis escaped without permanent damage in later years, and that unless a cure were found the patients would be permanently on their hands.

AN inquiry is being instituted by the *Dental Surgeon* into deaths under general anaesthetics by means of a questionnaire circulated among its readers with the issue of July 21st. An editorial article in the same number explains that this step has been taken in view of the wide difference of opinion which still seems to exist regarding the best anaesthetics for dental purposes. It is hoped to collect a mass of details as to the anaesthetics usually employed and their comparative safety for dental operations, and also as to the health of patients and particulars of any special preparatory treatment they may have undergone. The results after collation and classification will be issued in a suitable form, publication will be confined to details of medical and physiological interest and no names will be given. To make the inquiry successful by including within this survey every possible case of death under anaesthetics, the co-operation of all members of the medical and dental professions who are in possession of details regarding such cases is invited.

THE conference of port sanitary authorities at the Royal Sanitary Institute Congress at Plymouth on July 19th unanimously adopted a resolution "That the council of the Institute be recommended to direct the attention of the Government to the desirability of the care of the health of the men of the merchant service being placed in the charge of the Ministry of Health." The resolution was proposed by Fleet Surgeon W. E. Home, who was the author of a letter on this subject published in the *Journal* last week (p. 130), and seconded by Alderman F. Askew, chairman of the Hull and Goole Port Sanitary Authority.

At a joint council meeting of the People's League of Health, held on July 12th, it was decided to ask the Minister of Health to receive a deputation from the medical council of the league upon the need for the control and diminution of preventable noises in streets. The following have been asked to form the deputation: Sir E. Farquhar Buzzard, Sir Maurice Craig, Sir Robert Armstrong Jones, Sir James Purves Stewart, Dr A. T. Tredgold, Professor G. Robertson, M.D., and Dr Thomas Beaton.

At a meeting of the Metropolitan Hospital Sunday Fund held at the Mansion House on July 20th it was announced that the total sum collected this year amounted to £81,500.

DR FRANK M. HUGHES of Valmor, Kent, has been awarded the Médaille d'Argent de 1st classe de la Société Française de Sanvetege, Paris, with the diploma of honour.

A FURTHER section of the *Encyclopaedia of Industrial Health* has been issued by the International Labour Office, the pamphlet comprising Brochures Nos 109 to 114, and including the articles completing the publication of subjects coming under the letter "A." For binding, therefore, the appropriate brochures under this letter may be extracted from the temporary covers in which they have appeared separately and grouped together. The whole of the *Encyclopaedia* will be published also in volume form. Brochure No 109, of the latest issue, surveys the question of accidents in industry and the human factor, while the subjects of the others are rarefied air, aldehydes, ashes, atropine, auramine, aurantia, aurine, azobenzene and azo triphenyl methane. Another new pamphlet contains Brochures Nos 115 to 122, dealing respectively with bachelite, barium (compounds of), bark, benzene derivatives and benzidine, blismuth, blood and industrial poisonings, bontimon, bromine, and bronzing and bronze manufacture.

A FOLDING CARD has been issued by the Cambridge Instrument Company Ltd illustrating various installations of heating and ventilating plants in public and private buildings, including theatres, public offices, colleges, and Government buildings. A list of hospitals where such installations are in use is also given.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W C 1** on receipt of proofs.

All communications with reference to **ADVERTISEMENTS** as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561, 9562, 9563, and 9564** (internal exchange four lines).

The **TELEGRAPHIC ADDRESSES** are
EDITOR of the **BRITISH MEDICAL JOURNAL**, *Attology Western*
London

FINANCIAL SECRETARY AND BUSINESS MANAGER
(Advertisements etc.) *Articulate Western London*

MEDICAL SECRETARY *Medusca Western London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Incillus Dublin* telephone 62550 Dublin), and of the Scottish Office 7 Drumsheugh Gardens, Edinburgh (telegrams *Associata, Edinburgh*, telephone 24361 Edinburgh).

QUERIES AND ANSWERS

ARSENIOUS WAIL PAINT

"C D" wishes to know the best way of dealing with the painted walls of a dwelling house the paint of which has been found to contain an appreciable quantity of arsenious oxide. The occupant of the room has been found to be suffering with arsenical poisoning. Is there any preparation that could be applied to neutralize the arsenic left in the underlying plaster after the paint has been removed?

TREATMENT OF CHRONIC NASOPHARYNGEAL CATARRH

Dr JOHN DONALD (Glasgow) writes: I find that the only radical treatment is curtailing the nasopharynx. Change of climate is very important. The form due to atrophic rhinitis shows wonderful improvement after applying a vacuum electrode in each nostril from a high frequency current. The spark gap should be the smallest and the electrode of suitable size for comfortable introduction. Each sitting should last fifteen minutes, and benefit results even from one sitting.

CORNS

Dr A. L. MARTIN (Cranstock Cornwall) writes in answer to "H. A. A." (July 14th, p. 85): Corns so called are the result of focal pressure. Examine well the inside floor of the foot covering search for symptoms of flat foot. Above all soak the foot well in good soap and water really hot for twenty minutes then with a good razor, pare away all the horny matter taking care to get out the core without any haemorrhage—a little practice will suffice to ensure this, care as if preparing a microscopical specimen. Use powder in shoes or boots and avoid moulded footwear.

HAEMOPHILIA AND DENTAL EXTRACTION

Mr A. W. DAVIES (London W 1) writes: Your correspondent "A. P. A." (July 21st p. 137) may be interested to hear of a procedure I have adopted with success in these cases. It is absolutely essential to soile the teeth as if they were to be retained as well as any other teeth in the head. Oral sepsis must be combated with a suitable mouthwash. I have found none better than 1 dram of tinct iod. to the pint of 3 per cent carbolic acid. This also has the advantage of being an excellent deodorant. The extractions should never be done under local anaesthesia, but always in and on an operating table under general anaesthesia. Extractions should not be attempted in the surgery. The effort of getting home has always proved disastrous in my practice. A suitable blood coagulant is always administered. The one which has proved itself superior in my hands is coagulant oiba, 15 c.c. of this preparation is administered intramuscularly the noon of the day before the extractions, 15 c.c. more are given the same night and another 15 c.c. one hour before the operation, in the buttocks. The alveolus should be levered away from the teeth with very sharp thin elevators, and the tooth then removed with as little trauma as possible. As the patient is under general anaesthesia there is no point in hurrying. There is no better plug for a socket than the tooth removed from it, therefore, the extracted tooth has the apical one-sixteenth of an inch clipped off, the rough edges carefully rounded, and any readily available pulp removed. The pulp orifice is then sealed over with high heat gutta-percha and any debris or periodontal membrane carefully removed from the root. The tooth is then carefully hoisted and placed in sterile normal saline. The patient should be kept in bed for three days using the same mouthwash as previously used. Ice may be given to suck with advantage. The food should be entirely fluid. The case which proved most difficult

progressed favourably until the third day, when this patient opened the socket with some semi solid food. If haemorrhage sets in further doses of coagulant are given—15 c.c. every four hours. In critical cases intravenous injections may be given, but only with the most careful eye on the pulse, transfusion is also to be tried. The prepared teeth may be put back into the sockets and splinted into place. Their subsequent removal requires great care, or haemorrhage will again occur. Molars with markedly divergent roots are cut down until they may be inserted without scraping the sides of the socket. Care is required for a further week or so. Stimulants, exercise, and hot foods should be avoided, and the bowels should be kept active.

Dr A. B. LEAFLET (Golders Green) writes: I have had great success with small doses (100) of coagulant, 1 d.s. for four to seven days before the operation. In one case, when I had no time for this, I gave a hypodermic injection a few minutes before and used the coagulant orally after.

Dr S. G. PAPADOPOULOS (London, W 2) advises the following procedure: Give 5 grams of coagulant (powder) dissolved in 200 c.c. of water daily for five days by the mouth and on the sixth day inject hypodermically the contents of one tube of coagulant solution (20 c.c.). The patient will then be ready for the extraction. Any local bleeding can be arrested by sprinkling a little of the powder on the bleeding sockets. Further injections can be given hypodermically at any time without fear of anaphylaxis or other ill effects.

Dr E. BALDWIN and Mr A. W. RUSCOE (Golders Green) write to the same effect.

INCOME TAX Car Transactions

"D. M. M." bought a car in February 1925 for £260, and was allowed for depreciation £30 for 1925-27 and £30 as from 1927-28. In May, 1928, he bought a new car for £270, receiving £100 for his old car. What claim can he make?

* * * As the purchase of the new car took place in the financial year 1928-29, it does not affect his liability for that year. The depreciation allowance will therefore be based on the old figures and will amount to, say, £25. For the year 1929-30 his return will be affected in two ways: (1) he can deduct as a professional expense the obsolescence allowance due on the old car—that is, £260—(£100+£30+£25)=£260—£185 that is £75, and (2) the depreciation allowance due will be £270 at 15 per cent = £41.

LETTERS, NOTES, ETC.

A DISCLAIMER

Dr S. P. A. LEON and R. C. B. MACRAE wish to state that a laudatory letter which appeared in this *Pembroke County and West Wales Guardian* of July 13th was sent for publication without their knowledge or consent.

'THE FUTURE OF CRIME'

Our annotation headed "Crime and the Criminal" published on July 14th has brought a protest from Mr. George Godwin whose book *Crime or the Future of Crime* was discussed therein. His objects, among other things, to a comparison being drawn between a pamphlet on penal methods and an essay upon the much wider subject of the nature of crime and the problem of the delinquent member of society. In citing me, he writes, as having suggested that in the future it will be a crime to be financially successful, your reviewer misrepresents me. There is no such suggestion in my little book. What I did write was that great wealth will, likely enough, be regarded as a trust, an idea as old as Christianity. Neither is it anywhere suggested in my book, as your reviewer would have your readers understand that leisure will be a crime of the future. To suggest, as I did that the parasite poor or rascal, will not be tolerated is a very different proposition.

A CHOCOLATE BICENTENARY

Messrs J. B. TRY AND SONS, the well known manufacturers of chocolate and cocoa are this year celebrating the 200th anniversary of the establishment of their business and it is interesting to recall that the founder was a medical practitioner, Joseph Try a native of Wiltshire. An extensive practice in Bristol did not satisfy his ambitious and he embarked on a number of business ventures, including the small cocoa and chocolate shop which has expanded into the gigantic concern we know to-day.

CAUGHT NAPPING

In the paper on "Kidnapping," published on July 21st (p. 113), there is in the second column, a reference to the capture by Indiana of Peter Williamson as taking place in 1654. The date should, of course, have been 1754.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 42, 43, 46, 47 and 48 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 44 and 45. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 56.

Observations ON UNSUCCESSFUL FORCEPS CASES

CAUSATION, MANAGEMENT, AND END RESULTS *

DOUGLAS MILLER, M.D., F.R.C.S. Ed.,

Lecturer in Clinical Obstetrics and in Clinical Gynaecology,
University of Edinburgh

The anxiety which follows the unsuccessful application of forceps, the difficulty of determining how best to effect delivery whether the patient is kept in her own home or transferred to hospital, and the frequency with which life is lost or serious disability incurred combine to invest the "unsuccessful forceps case" with special importance and make it a subject peculiarly suitable for discussion at a meeting of this kind.

The contribution which I would make is based on the study of 558 cases. I am indebted to Professor Fletcher Shaw for placing at my disposal the records of 281 patients delivered in Manchester, and to Professor Hendry of Glasgow for the details of a further 125 cases. The remaining 152 patients were delivered in the Edinburgh Royal Maternity Hospital.

ETIOLOGY

An analysis of these cases shows that in 211, or in rather more than one-third of the total number, the underlying cause of dystocia was disproportion, due for the most part to pelvic contraction, and in a small number to abnormal size of the child. The pelvis were chiefly of the flat rachitic and generally contracted types, the former variety predominating, especially in the Glasgow series. In 14 cases deformity of the pelvic outlet was encountered. In 6 cases a contraction ring of the uterus was an additional obstacle to delivery.

The degree of disproportion varied within wide limits. In more than one-half the head was found to be still freely movable at the pelvic brim when the patient was admitted to hospital, in many disproportion was so extreme that even when the head was crushed much difficulty was experienced in its extraction. In other cases the head was engaging satisfactorily in the brim and would have descended normally to the pelvic cavity had assistance been withheld to allow of further moulding and of more complete dilatation of the birth passages.

A posterior position of the occiput was found to be an almost equally common cause of difficulty, and was encountered on 161 occasions. Twenty-two additional cases in which this abnormality was associated with pelvic contraction have been included in the category of the latter. In a few the malposition had been recognized as such, as a rule after moderate forceps traction had failed. For the most part, however, the cause of obstruction had not been appreciated, the delay in labour being commonly attributed to a contraction of the pelvis which did not exist. The frequency with which such an error in diagnosis causes difficulty emphasizes the importance of accurate orientation of the head as a preliminary to the application of forceps, in this connexion the ear is a more reliable guide than are sutures or fontanelles, and in doubtful cases should always be sought for.

In the majority of these cases of occipito posterior position it was found, on admission, that the head was deeply engaged, with the occiput either in the hollow of the sacrum or still obliquely posterior. In a considerable number, however, the head was still high in the cavity or movable at the pelvic brim. Such cases in particular frequently showed severe bruising and laceration of the soft parts from slipping of the forceps. In many in which a high forceps operation had been attempted the cervix was only partially dilated, and was as a rule, more or less seriously torn, in seven cases a tear in the cervix had extended upwards so as to involve the lower uterine segment.

A third group comprises cases, 151 in number, in which no abnormality of the pelvis was present, the child was of average size, and presentation and position were normal. It is possible that some of these were patients in whom an occipito-posterior position had been present when forceps delivery was first attempted, rotation of the occiput to the front having occurred during the patient's transit to hospital. In a large number, however, no obvious explanation of failure could be found, or it was apparent that anxiety to relieve suffering had prompted an attempt to assist delivery before sufficient dilatation of the soft passages and adequate head moulding made this practicable. In many of these patients the first stage of labour through premature rupture of membranes, rigidity of the cervix, or ineffective uterine contractions, had been unusually prolonged and difficult. We all know how trying such cases may be and how easily the anxiety or impatience of relatives may combine with mental and physical fatigue to unbalance judgement and invite unwise intervention.

As in many cases of contracted pelvis and occipito-posterior position above referred to, so in this group intervention failed largely because it was premature. Of necessity, serious injury to cervix and vagina was not infrequently entailed.

Finally, in a fourth group in which forceps delivery was unsuccessfully attempted there fall to be catalogued 12 face cases, 5 of them mento-posterior, 8 cases of brow presentation, 8 cases of hydrocephalus, 2 cases of breech presentation, 2 cases of shoulder presentation, 2 cases of ovarian tumour obstructing labour, and 1 case of locked twins.

TREATMENT

In a communication read at the Annual Meeting of the British Medical Association a year ago I discussed the diagnosis and outlined the general principles of treatment which should govern the management of the failed forceps case. To-day I would concern myself shortly with the different methods of treatment which have been employed, and indicate what the results, immediate and remote, have been.

In general, treatment varied with the cause of failure and with such other conditions as the degree of disproportion, the presence and extent of injury to the birth passages, and the general condition of mother and child. Shock, consequent on severe trauma and intensified by transport to hospital, often over long distances, was not infrequently a serious complication, and was a primary consideration in the treatment of many cases. On occasion it was so profound as to make the outlook one of the utmost gravity, irrespective of whatever method might be employed to effect delivery.

Dystocia due to Disproportion

There were 211 such cases, in 139 of these the patients were primigravidae, where previous pregnancies had occurred a history of difficult labour was commonly obtained. The management of cases in this group was influenced largely by such factors as the degree of disproportion, whether or not there had already been an adequate test of labour and the condition of the child. In approximately one-half of the total number the child was judged to be already dead or dying at the time of the patient's admission to hospital.

In many cases it was apparent that, with further moulding of the head, such disproportion as was present could adequately be overcome by the natural forces. Reference to Table I will show that in 78 patients, in whom earlier intervention had failed spontaneous delivery eventually occurred or was accomplished by low forceps. Further, in many cases in which craniotomy was employed spontaneous delivery would probably have occurred had not this operation been performed merely to facilitate the extraction of a child already dead.

In other patients disproportion was so marked as to preclude any possibility of delivering the child alive by the natural passages. In such circumstances there arose the difficulty of deciding which of the two operations, Caesarean section or craniotomy, entailed the less serious risk.

* A paper read in opening a discussion in the Section of Obstetrics and Gynaecology of the Annual Meeting of the British Medical Association, Cardiff 1928.

Farquhar Murray has recently drawn attention to the difficulty and danger which craniotomy entails in the presence of serious disproportion, and has strongly urged more frequent resort to Caesarean section in such cases, even where there is undoubted infection and the child is dead. On the other hand, the statistics of Holland and Kerr and of Routh indicate clearly how much more grave is the prognosis where Caesarean section is done in the potentially septic than in the "clean" case, the mortality in the former varying from 10 to 34 per cent.

In the series of cases now presented Caesarean section was performed on twelve occasions, with three maternal deaths and five stillbirths. While such material does not afford an adequate basis of comparison of the relative merits of the two procedures, the trend of modern obstetrical opinion is reflected in the comparatively small number of cases in which abdominal delivery was preferred. In Edinburgh, however, the tendency in recent years has rather been to increase the scope of Caesarean section, so as to avoid the extreme mechanical difficulty and severe trauma which may be associated with a high craniotomy for marked disproportion.

It is significant that in none of the three centres from which the cases under analysis have been drawn was delivery in any case effected by pubiotomy.

Of the 29 maternal deaths in this group, 21 were due to puerperal sepsis, 3 to post-partum shock, 2 to post-partum haemorrhage, 2 to shock and collapse associated with rupture of the uterus, and 1 to pneumonia.

TABLE I—Analysis of 211 Cases of Dystocia due to Contracted Pelvis

Method of Delivery	No of Cases	Children Dead or Dying on Admission	Maternal Deaths	Foetal Deaths
Spontaneous	13	6	0	7
Low forceps	65	15	3	27
High forceps	15	2	2	11
Version	8	1	2	6
Craniotomy	98	22	20	93
Caesarean section ..	12	3	2	5
Total	211	109	29	154

Dystocia due to Occipito-posterior Position

There were 161 such cases, rather more than half of whom were primigravidae. This figure is exclusive of 22 cases in which pelvic contraction was also present, but includes a large number in which incomplete dilatation of the cervix had contributed to dystocia.

The treatment of cases in this group depended largely on the level in the pelvis which the head had reached, on whether or not the cervix was fully dilated, and on the condition of the child. In the majority of cases the patient was advanced in the second stage of labour with the head arrested on the pelvic floor. In such circumstances an attempt was made, as a rule, to correct the malposition by manual rotation and thereafter to complete delivery with forceps. Occasionally the head was found to be impacted so firmly as to make manual rotation impossible, for the most part in such cases no hope could be entertained of the child being born alive, and craniotomy was performed, in a few, however, a living child was extracted face to pubes.

Not infrequently it was found that the head was arrested in a posterior position at the inlet of the pelvis or upper part of the pelvic cavity. In approximately two-thirds of these cases manual rotation of the head, combined with external rotation of the body, was carried out. In those in which the os was found to be fully dilated this was generally followed by the immediate application of forceps and delivery completed, in others, in which the cervix was not completely effaced, further intervention had necessarily to be withheld until a later stage in labour. In contrast to the previous delay the rapidity of progress after correction of the malposition was, as a rule, gratifying, and in many cases almost dramatic, in a relatively large number, moreover, no additional assistance was required.

Internal version was a method employed in eleven of these cases of high arrest. Although only three of the children were saved, it should be pointed out that the procedure was employed for the most part as a last resort, after other methods of delivery had failed, and was undertaken in preference only to craniotomy, since the foetal heart could still be heard.

Finally, Caesarean section was performed on three occasions, in two cases a rupture of the lower uterine segment, which had extended upwards from a cervical tear, provided the indication for opening the abdomen, in the third case a marked contraction ring of the uterus made vaginal delivery impossible. All three of these patients recovered, and in one case the child was born alive. There were sixteen maternal deaths in this group, the causes being sepsis, 11 cases, rupture of uterus, 4 cases, pneumonia, 1 case.

TABLE II—Analysis of 161 Cases of Dystocia due to Occipito-Posterior Position

Method of Delivery	No of Cases	Children Dead or Dying on Admission	Maternal Deaths	Foetal Deaths
Spontaneous	15	4	1	6
Forceps	95	26	8	46
Version	11	3	1	9
Craniotomy	37	22	6	37
Caesarean section ..	3	1	0	2
Total	161	62	16	100

Dystocia due to Premature Application of Forceps

There were 151 cases in this group. Where no cause for failure was found other than that forceps had been prematurely applied, treatment was governed by the extent to which labour had progressed and by the general condition of the mother and of the child. In the majority of these cases the patient was placed under the influence of morphine or of twilight sleep, and labour allowed to proceed until delivery occurred spontaneously or could be completed by a low forceps operation. Where the child was already dead or dying craniotomy was commonly performed to make easier its extraction. In two cases in this group a traumatic rupture of the uterus necessitated abdominal delivery. In a third case of rupture of the uterus forceps had apparently been applied outside the cervix, the patient was admitted in a condition of extreme collapse and died within a few minutes of her arrival in hospital. There were in this group 9 maternal deaths, 5 of which were due to sepsis, 2 to rupture of the uterus, 1 to post-partum shock, and 1 to pneumonia.

TABLE III—Analysis of 151 Cases of Dystocia due to Premature Application of Forceps

Method of Delivery	No of Cases	On Admission		Maternal Deaths	Foetal Deaths
		Incomplete Dilatation of Cervix	Children Dead or Dying		
Spontaneous	47	20	8	1	15
Forceps	75	41	24	6	37
Version	9	6	3	1	7
Craniotomy	18	12	18	0	18
Caesarean section ..	2	2	1	1	1
Total	151	81	52	9	78

END-RESULTS

The tragic loss of life, maternal and foetal, associated with different types of unsuccessful forceps cases has already been referred to in different parts of this paper. In all, 54 patients died, a mortality of 10 per cent, and one which is scarcely exceeded by any of the major complications of pregnancy or labour. The individual causes of death were sepsis 37, rupture of the uterus 8, post-partum haemorrhage and shock 6, and pneumonia 3.

In addition, in 132 cases (23.6 per cent of the total series) the puerperium was morbid according to the British Medical Association standard. Many of the patients recovered sufficiently to leave hospital only after exhausting weeks of fever. Including stillbirths and neo-natal deaths 357 of the infants were lost—a mortality of 64 per cent.

Such figures indicate only too clearly how anxious must be the prognosis where an injudicious use of forceps results in failure to effect delivery. The full significance of such failure lies, however, not only in the immediate grave risk to life which it involves, but also in the frequency with which crippling invalidism may follow as the result of infection or injury sustained. Few patients escaped without more or less serious laceration of the cervix, vagina, or pelvic floor, sloughing of the vaginal tissues with fistula formation occurred in several cases. Further, it will be appreciated that a primary repair was seldom feasible or successful. Many patients were perforce discharged only to face further weeks or months of ill health.

So that the extent of subsequent disability might be determined it was decided to make a follow-up study of such patients in this series as were delivered in the Edinburgh Royal Maternity Hospital. In all, 116 patients were communicated with and asked to report at the hospital for examination. Of these, 18 did not respond or could not be traced. The end-results of 98 cases, however, are available, and may be summarized as follows.

In 24 cases, or roughly one-fifth of the total, the patient stated that her health had not in any way suffered, and pelvic examination revealed no abnormality of importance. The remaining 74, however, had all suffered varying degrees of inconvenience or discomfort, sometimes amounting to serious ill health, in almost all of these one found stigmata of the ordeal through which they had passed.

Laceration of the cervix, with or without downward displacement of the uterus, was the lesion most commonly encountered in this follow-up investigation. The frequency with which such an injury was found is of special importance, in the first place it emphasizes how commonly in unsuccessful forceps cases of all types failure is the result of an attempt to complete delivery before the cervix is fully dilated and therefore before the patient has had the benefit of the second stage of labour. The corollary is likewise apparent injury to the cervix and to the upper supporting structures of the uterus must inevitably occur where forceps are applied before the cervix has fully retracted over the presenting part.

Backward displacement of the uterus was present in a considerable number of cases. In a few the condition was unaccompanied by any other pelvic abnormality. In the majority, however, it was associated with subinvolution, with downward displacement, or with pelvic infection, of itself the retroversion was probably of less importance than were the other conditions of which it was a complication.

Pelvic infection, evidenced by chronic subinvolution, impaired mobility of the uterus, or by enlargement and abnormal sensitiveness of the uterine appendages, was found in approximately one-third of the cases examined. In greater or less degree it was met with in almost every case in which the puerperium had been febrile. These patients complained of symptoms varying from minor discomfort to more or less constant and acute misery. In most, such relief as medical measures could offer had already been afforded, and for many the ordeal of a major operation was the only alternative to continued ill health.

Twenty-four patients of those who reported had been subjected to operation for disability resulting directly from the type of dystocia under consideration. In 10 cases a reparative procedure had been carried out for injury to cervix or pelvic floor, in 3 cases an operation for vesico-vaginal fistula had been performed, 4 patients had been cured for menorrhagia, in 6 cases hysterectomy or the removal of the uterine appendages had been called for. There had in addition, been one operation for extra-uterine gestation. The majority of these patients now enjoy reasonably good health.

In 19 patients of those who reported, subsequent pregnancy had occurred, in 13 cases the pregnancy had proceeded normally to successful delivery at term, in 5 patients

abortion had occurred, and in one case the gestation had been extrauterine in type.

For the rest, in whom after a reasonable interval conception had not occurred, many admitted that through apprehension of its dangers pregnancy was being avoided. There were others whose chief concern was that they had been denied the privilege of a second chance, and for whom the suffering and danger to life which they had been called on to face had meant less than the disappointment of an empty cot.

Such, in brief, is a record of the consequences which may follow ill-timed or misdirected efforts to supplement or supplant Nature's methods. To what extent the unsuccessful forceps case is the indirect outcome of inadequate undergraduate training, of insufficient co-operation between midwife, family doctor, and consultant, or of defective municipal or public health administration, is open to question. Of this broader aspect of etiology Professor Fletcher Shaw has spoken. More directly it is manifest that many of these disasters could have been prevented by ante-natal recognition of contraction of the pelvis, undue size of the child, or other abnormality.

In its immediate causation the unsuccessful forceps case would appear to be, very largely, the outcome of non-observance of one of three elementary rules in regard to forceps operation. First, that forceps should not be applied in the presence of marked disparity in relation to the head and pelvis, and rarely, if ever, when the head is still movable above the pelvic brim. The frequency with which it was found that forceps delivery had been attempted while the head was still unengaged would indicate that the difficulty and danger of the high forceps operation are not sufficiently appreciated. Secondly, that forceps should not be applied without an exact knowledge of the position which the head occupies in the pelvis. The initial mistake in unsuccessful forceps cases is so frequently one of diagnosis that it would appear necessary to re-emphasize the wisdom of the time-honoured dictum "chloroform and the whole hand" as a preliminary to forceps application. The third essential is that the cervix should be completely effaced and retracted over the presenting part. On so elementary a proviso to the safe use of forceps one would hesitate to insist, were it not so frequently disregarded.

To remove the stigma which to day attaches to the practice of midwifery by giving effect to such recommendations as various committees of inquiry have made may be an extravagant hope. To insist that forceps should not be applied unless on strict obstetrical indications may be a counsel of perfection. To save many lives which need not be lost and to relieve the burden of much avoidable suffering by a greater discretion and care in the use of forceps—this, surely, is an ideal which we may reasonably cherish.

UNSUCCESSFUL FORCEPS CASES

HOW FAR CAN THEY BE PREVENTED BY EFFICIENT ANTE-NATAL CARE?

BY

JAMES HENDRY, M.A., B.Sc., M.B., F.R.C.P.S.G.,
Muirhead Professor of Obstetrics and Gynaecology Glasgow
University Visiting Physician Glasgow Royal Maternity
and Women's Hospital Gynaecologist Glasgow
Royal Infirmary

In this newspaper age, is there any citizen who has not been made aware of the unsatisfactory state of obstetric practice in this country? Hardly a week passes without some reference in the lay press to conferences on maternal mortality to questions in Parliament on the same subject, or to the appointment of departmental committees—for example—to advise upon the application to maternal mortality and morbidity of the medical and surgical knowledge at present available. Obstetrics is made to appear the Cinderella among the ashes while her gorgeously arrayed sisters, Medicine and Surgery go to the ball. Occasionally the dignified weekly or monthly reviews enter the lists. Not many weeks ago the *Spectator's* champion, a well-equipped Crusader, arraigned the General Medical

* Read in a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association Cardiff 1923.

Council for the inadequate teaching of medical students, arraigned the streptococcus as the cause of puerperal fever, and then arraigned "the busy doctor, the perturbed father, and the weany mother" for "meddlesome midwifery" which introduced the streptococcus. His plea was for the extension of ante-natal supervision and treatment.

Interest in this subject has permeated every home in the land. At a very important meeting in the Westminster Central Hall, London, on February 28th, 1928, attended by representatives from county nursing associations, infant welfare centres, and maternity and child welfare committees, a message was read from our gracious Queen Mary that she "viewed with grave concern the continued high rate of maternal mortality, and felt that a very real endeavour should be made to remove this reproach from the national life. The Queen trusts this may be achieved through the education of mothers themselves in the need for ante-natal care, through inquiry into the immediate causes of mortality in childbirth, and through a wider provision of first-class medical and midwifery service."

The members of the medical profession need be under no misapprehension as to whom the public are being encouraged to hold responsible for the high maternal mortality and morbidity rates. At that Central Hall meeting, attended not only by the representatives I have referred to, but also by Sir George Newman and Dame Janet Campbell of the Ministry of Health, Lady Solborne is reported to have crystallized the feeling of many present in her statement that "there is danger in the doctor." This is almost the identical phrase used by that famous midwives' champion of the eighteenth century, Mrs. Nihell, in her diatribes against the "men-midwives" of that time, among whom were the illustrious Smellie and William Hunter.

In the present discussion we are not concerned with any consideration as to how or by whom obstetric practice should be conducted. We are simply analysing a series of actual cases in which instrumental interference was unsuccessful. Dr. Miller has dealt with the actual records. My special duty is to consider how far these cases of unsuccessful instrumental intervention could have been prevented by more efficient ante-natal care.

CONTRACTED PELVIS

Dr. Miller's figures show that in more than one-third of the cases there was disproportion between the presenting part and the pelvis. In only a very small number was this due to unusual size of the child. It is, of course, well known that the incidence of contracted pelvis varies in different districts, while the average in all three sets of figures is about 33 per cent, the incidence in the Glasgow series is actually 50 per cent, and an unusually large number of these are of the flat rachitic type.

A very large number of these cases could be identified early in pregnancy. Need I refer here to the fact that many of these women have very striking evidence of skeletal deformity—namely, stunted growth, spinal curvature, sword-blade tibiae, etc? I should like to mention specially the relationship between kyphotic spinal deformity and contracted pelvic outlet, and between lameness, where the weight of the body has been from childhood borne on one thigh, and unilateral pelvic deformity. I do not dispute the fact that gross deformity may accompany a roomy pelvis, but skeletal irregularity should be a danger signal.

While external pelvimetry—that is, the measurement of the interspinous, ischioristal, and external conjugate diameters—only gives an estimate of the inside pelvic diameters, irregularities in the former emphasize the necessity for internal examination. The form of the pelvic outlet should always be examined. A sharp subpubic angle, with the distance between the ischial tuberosities reduced, indicates contraction at the outlet, without such an examination this abnormality might escape notice until late in labour, because in such a case the head often passes easily through the brim and is only arrested low in the pelvis.

An examination of the diagonal conjugate diameter should always be attempted. There are many women in whom an attempt at this measurement per vaginam may be extremely difficult in the early months, an attempt

during the seventh or eighth month, however, is usually successful owing to the increasing softness of the parts. Where the examination is still difficult then, a certain amount of assistance is got by asking the patient to "bear down" during the examination, thus relaxing the perineal muscles. I have heard both students and practitioners assert that they were greatly handicapped by short fingers, but I submit respectfully that there are few fingers too short to measure the diagonal conjugate in the case which is likely to cause difficulty. In the series of cases which I have investigated I found the estimated true conjugate to be $3\frac{1}{2}$ inches in 19 cases, 3 inches in 14 cases, $2\frac{1}{2}$ inches in 9 cases, and $2\frac{1}{2}$ inches in 2 cases. In four of them craniotomy was extremely difficult owing to the small size of the pelvis. In all of them internal pelvimetry should have been fairly easy.

An estimation of the diagonal conjugate is not a complete examination of the interior of the pelvis. The examining fingers should always sweep round the pelvic brim in this way many cases of asymmetrical deformity will be identified. In particular, the generally contracted pelvis, where the true conjugate diameter may be normal while the transverse diameter is markedly diminished, can be identified. I shall refer later to the fact that such an examination should also identify fibromyomata or ovarian cysts likely to give rise to grave difficulty in labour.

Towards the end of pregnancy there are other methods of identifying cases of contracted pelvis. A pendulous abdomen in a primigravida should always arouse suspicion. Again, in a primigravida the head should descend into the pelvic cavity during the last month. While the non-descent may be due to faulty presentation, neoplasm, or even placenta praevia, it is very often due to contracted pelvis. In forty-six cases of failed forceps in primigravidae in my series, the head was still free above the brim in twenty cases when the patient was admitted to hospital.

Again, at this stage the best of all pelvimeters—namely, the foetal head—is available. The most convenient way of using this pelvimeter, in my experience, is the modification of Muller's method, so long advocated by Professor Munro Kerr. If there is the slightest doubt about any case, I should recommend most strongly that an examination by this method be made under an anaesthetic within the last month. I should like to point out here that while diagrams may show the fingers in the pelvis with the radial borders towards the foetal head, it was never intended that the complete examination should be made in this position. No one would ever make such an examination except with the palmar surfaces of the fingers. It is not only the relationship of the head to the true conjugate which should be examined, but the engagement of the whole surface of the presenting part to each point of the pelvic brim.

There is an essential difference in the examination and prognosis of a case of generally contracted pelvis as compared with a flat rachitic pelvis. In the latter the amount of space available in the lateral bays on each side of the promontory is of great importance. In a favourable case the head engages transversely and makes its way through the brim by the descent of the occipital and through one bay. In a generally contracted pelvis, however, the total area of the brim is small and the head can only pass through in extreme flexion. This extreme flexion makes traction with forceps difficult, as only an insecure hold is obtained.

One would hardly think it necessary to mention the fact that the history of previous labours in a case of contracted pelvis is most valuable. In spite of this I have investigated seven cases of failed forceps in which the only previous pregnancy had terminated in a difficult instrumental stillbirth, two in which both previous pregnancies had terminated in instrumental stillbirths, and one where one previous labour had terminated in a craniotomy and the other in an instrumental stillbirth. There was still another case with a history of five previous difficult instrumental labours with two stillbirths.

In discussing the value of ante-natal examination in contracted pelvis I have not made any mention of x-ray examination of the pelvis. Absolute measurement by x-rays is not of great value except in extreme cases, and

thoro examination of the diagonal conjugate is relatively easy. In borderline cases the foetal head is the true pelvimeter, and on its position at the brim before the onset of labour does not give any indication as to how it will mould or alter its position and relationship under the influence of uterine contractions. Munro Kerr's method of pelvimetry gives a far more reliable prognosis.

In the generally contracted pelvis I believe that there is a field for x-ray examination. In a recent publication Professor Martius of Göttingen has recommended a projection method of pelvimetry for such cases.¹ The patient is placed in a position resembling Fowler's position, so as to bring the pelvic brim parallel to the table. Using a fixed focal length, and knowing the height of the pelvic brim above the photographic plate, it is possible to calculate the actual area of the pelvic brim. Professor Martius believes that a normal-sized foetus cannot come through such a pelvis when the area of the brim is less than 70 or 80 square centimetres.

In all this reference to contracted pelvis I have claimed that it is possible to foretell difficulty. Cases suitable for induction of labour may be identified from the thirty-sixth week onwards. When a patient with a known deformity is allowed to go on to term it is advisable to have the patient admitted to hospital at the onset of labour, or at any rate to have her regarded from the beginning of labour as one in whom even Caesarean section may become necessary. The result of the labour will depend not only on the degree of disproportion, but also on the mouldability of the head and the strength of the uterine contractions.

If the use of forceps is decided on, a most careful re-examination of the patient should be made after she has been anesthetized—if necessary, with the hand in the vagina. In this way the position can be accurately diagnosed. If there seems likely to be great difficulty it is better to stop with this examination rather than to endanger the mother and damage the child by violent efforts at delivery. I have myself had the mortification of performing Caesarean section in a "failed forceps" case, and delivering a child with a fractured skull and both cheeks very badly torn by the forceps.

In such cases the number of vaginal examinations should be kept to a minimum. Rectal examination can become, with practice, just as satisfactory and certainly less dangerous. We have all been warned how much graver becomes the prognosis in a Caesarean section case with each vaginal examination.

In borderline cases of contracted pelvis my own preference is to allow the patient a good long labour, and then, if progress is not satisfactory, to perform the lower uterine segment Caesarean section. The longer the patient has been in labour, within limits, the easier is the operation.

Occipito-posterior Positions

Dr Miller's analysis shows that occipito-posterior positions were present only slightly less frequently in the series of "failed forceps". In comparatively few of these cases had the abnormal position of the occiput been recognized before the application of forceps, and in very few had any attempt been made to correct the position before using them. In some it would appear that the traction merely accentuated the malpresentation.

Careful ante-natal examination can usually identify occipito-posterior positions. There are some cases in which a particularly thick or specially sensitive abdominal wall does make such an examination difficult. The ease with which limbs are palpated in front and the easy identification of the foetal chin are useful guides. Where palpation is difficult a couple of x-ray photographs, frontal and lateral, should give a complete diagnosis.

There is some difference of opinion as to whether occipito-posterior positions can be corrected before the onset of labour. While many hospital workers have reported disappointing results in this direction, Dr Haultain, two years ago, published a series of cases in which he secured permanent correction by the use of pads and a binder in 87 per cent of the primigravidae, and in 83 per cent of the multiparae.² Dr Haultain stressed then the importance of carrying out this correction in the last month

of pregnancy, and particularly in cases where the head remained free above the brim. The successes originally reported by Dr Buist, and by many who have followed him, should have gained more widespread employment of this method of correction. Even where no attempt has been made to correct an occipito-posterior position before the onset of labour, we must remember that certainly 60 per cent, if not quite the 80 per cent referred to in most textbooks, do rotate spontaneously. The important point is to recognize the association of this malposition with a protracted labour.

When the abnormal position has not been recognized before, it should never escape notice when the patient is examined before the application of forceps. Even a very firm and extensive caput succedaneum should not obscure the diagnosis. When forceps are applied while the head is still in the occipito-posterior position, especially when it is high in the pelvis, they certainly do slip easily.

Associated with this position of the vertex, as also in cases of contracted pelvis, there is often slow dilatation of the cervix. In 50 per cent of my series of cases in which forceps had been unsuccessfully applied in occipito-posterior positions the cervix was still incompletely dilated when the patient was admitted to hospital.

OTHER ABNORMAL PRESENTATIONS

Face and brow presentations do not occur until the onset of labour, except under most unusual circumstances. While such abnormalities cannot, therefore, be identified during pregnancy, the conditions likely to give rise to them may be. Of these the most important are bony deformity of the pelvis and obliquity of the axis of the uterus. While both can be identified, the latter can often be effectively treated by the use of a binder. Unusual size of the foetus and hydramnios can both be identified before labour comes on, but such other causes as anencephaly, meningocelo, and congenital goitre can hardly be diagnosed in advance.

Transverse and oblique presentations should be identified before the onset of labour. They may be corrected in the cases where a lax abdominal wall is responsible. Where the cause is a contracted pelvis, a malformed uterus, or a neoplasm, the early recognition of the cause will allow arrangements for proper treatment to be made.

While breech presentations hardly come within the scope of this paper, there are two cases in the series where forceps were unsuccessfully applied to an undiagnosed breech. At that stage careful examination should have made a diagnosis easy. In breech presentations, especially in primigravidae, the important point is to have version performed before the onset of labour. This presumes timely diagnosis by palpation, which may be difficult. In cases of this type x-ray examination is most helpful, not only in arriving at a diagnosis, but also in indicating in which direction the foetus should be turned.

TUMOURS

Uterine and ovarian tumours appear only twice in our series of cases. They can almost always be identified before the onset of labour, and in fact are usually noticed at the first pelvic examination. Whenever such a diagnosis has been made the patient should be in some institution at the onset of labour, so that major surgical interference may be carried out without delay, should it become necessary.

FOETAL ABNORMALITIES

In eight cases of the series the difficulty was due to hydrocephalus. Among all foetal abnormalities this is probably the one most easily diagnosed before the onset of labour. The outline of the large soft head can generally be identified, except where it is obscured by hydramnios. When it has been recognized perforation, after about a three-finger dilatation of the cervix is reached, may prevent an exhausting labour.

General foetal dropsy is generally associated with some other abnormality, such as an abnormal presentation, and the over-distension of the uterus should determine the patient's transference to hospital.

Foetal monsters often escape notice until the actual appearance of dystocia, as the presenting part may be of

normal proportions and in normal position. The difficulty of diagnosing anencephaly and congenital goitre has already been referred to.

CASES OF INCOMPLETE DILATATION OF THE CERVIX

In discussing occipito-posterior positions I referred to the slow dilatation of the cervix in such cases. In my series of 68 cases of contracted pelvis in which forceps had been unsuccessfully applied, the cervix was still incompletely dilated in 33 of the cases when the patient was admitted to hospital. In two of this group the dilatation was of such slight degree that it was difficult to imagine how forceps could ever have been applied to the foetal head. In all these cases there was a definite cause for the delayed labour and the slow dilatation of the cervix, but in 151 of all the cases reviewed by Dr. Miller there was no evidence of any abnormality, yet forceps had been applied before the cervix was fully dilated. In the 34 cases which I contributed to this group one mother died from rupture of the uterus, five had a morbid puerperium, but the remainder had an uneventful recovery. There are probably many of these women who will still require treatment in gynaecological wards, because traction through an undilated cervix causes not only tearing of the cervix, but also forced descent of the cervix with subsequent uterine prolapse. However, it is when we consider the results to the child that the picture is blackest. Of the 34 children 15 were stillborn, and several of the survivors showed extensive bruising at birth.

I think we must agree that the application of forceps before complete dilatation of the cervix is a most dangerous procedure, yet we see how often it appears to have been practised. Efficient ante-natal care should identify the cases where labour is likely to be protracted and dilatation slow, but it is only effective teaching which can prevent the too early application of forceps in normal cases. From my experience as a teacher I know that on questioning students there is hardly one who does not remember to state that the cervix must be fully dilated before forceps are applied.

The point on which I think teachers and textbooks do not lay sufficient emphasis is that manual dilatation of the cervix is seldom justified, and, even when it is attempted, is very often incomplete. I have even been informed by a young graduate, negotiating for the admission of his "failed forceps" case to hospital, that he had first used gentle traction with the forceps to secure dilatation of the cervix. The patient eventually delivered herself spontaneously.

CONCLUSION

In estimating how far the cases of "failed forceps" could have been prevented by efficient ante-natal care, I have tried to show that almost all of the real abnormalities could have been identified during the course of pregnancy, and particularly in the last month. There is only a very small group of foetal abnormalities of the developmental type which cannot be detected before the onset of labour. Ante-natal supervision, however, cannot prevent the too early application of forceps in normal cases.

When abnormalities have been detected they may either be corrected before the onset of labour, as in occipito-posterior, breech, and transverse presentations, or sent to a hospital or similar institution where appropriate treatment can be carried out in the most favourable circumstances at the correct stage in labour.

It may be asked whether the ante-natal supervision to which I have referred can be efficiently carried out by the family physician. In many cases it can, but there must always be a considerable proportion of cases in which accurate diagnosis of pelvic disproportion or abnormal presentation is difficult, even for the hospital physician with special training. He may require the help of x-rays to establish his diagnosis. It would appear, therefore, that an efficient obstetric service would require well-equipped consultative ante-natal centres to which the cases presenting difficulties to the family physician can be referred. Again, work of this kind is far too responsible and difficult for midwives, and I believe that a midwife

should not be authorized to undertake the care of any pregnant woman without provision being made for the patient to be examined carefully by a medical practitioner before labour is due.

UNSUCCESSFUL FORCEPS CASES *

BY

WILLIAM FLETCHER SHAW, M.D., CH.B.,

Professor of Clinical Obstetrics and Gynaecology, University of Manchester, Honorary Gynaecological Surgeon, Manchester Royal Infirmary

In the last few years more and more attention has been focused upon maternity practice, meetings of various bodies outside the profession have discussed the subject, often with great ignorance of the facts, and necessarily, from the composition of these meetings, the blame for the present high mortality in childbirth has been thrown upon the members of our profession.

In the great majority of instances these charges are an injustice, and a slight knowledge of the facts would prevent them from being made, but in some directions obstetric practice leaves much to be desired, and it behooves us, as a profession, to take stock of our methods and see if it is not possible to raise the standard. It is for this reason only that we have brought forward this subject for discussion before a meeting composed largely of general practitioners. We have stated our views as members of the staffs of maternity hospitals, and we hope that general practitioners will fully state their views, and that the discussion will bear fruit. In similar discussions in the past it has often been stated that the consultant speaks only from his experience of hospital work, and compares his own results in ideal circumstances with those of men who have to conduct their cases in circumstances far from ideal. The fact is overlooked that few consulting obstetricians reach the staff of their hospital without an extensive experience of maternity work in the very poor quarters of their cities, and therefore are fully alive to all these disadvantages. One advantage, and one only, had we over the general practitioner—we were doing obstetrical work only, and had no anxiety about other cases being neglected when we were engaged for a long period over one maternity case. If this is a factor in bad midwifery, and I feel sure it is one of the most important, it is better to face the facts and see if a remedy cannot be found.

The aspect of maternity work we are considering to-day is one of the greatest blots on our obstetrical escutcheon. The figures given by Dr. Miller occurred in the practice of three large maternity hospitals, but these hospitals were chosen at random, and there is no doubt that equally convincing figures could be produced from every other maternity hospital in the country. The facts are there and are incontrovertible. Dr. Miller has shown the types of cases which result in forceps failure, and has analysed the causes and discussed the diagnosis and treatment. He has also detailed the appalling results to mother and child, results which could have been avoided with a little more care and knowledge.

One of the most striking figures in this series is the large number of craniotomies performed. In the last twenty years the number of Caesarean sections performed in each obstetrical unit has enormously increased, and the first thought on seeing these figures is that many of these children could have been saved by this operation. In considering this alternative treatment we must remember in the first place that the majority of the children were dead or badly damaged when the patient was admitted to hospital, but a small number were alive and were deliberately sacrificed to save the mother.

Caesarean section performed upon a "clean" patient is now a safe operation with a very low mortality, but Caesarean section performed upon a patient after attempts

* Read in a discussion in the Section of Obstetrics and Gynaecology of the Annual Meeting of the British Medical Association, Cardiff 1928.

at forceps delivery is a very different matter, and is followed by a dreadfully high maternal mortality. Eardley Holland¹ in 1921, in a collection of 3,374 cases from the large maternity hospitals of the British Isles, showed that the mortality in cases in which the operation was performed before the onset of labour was only 1.6 per cent, whereas in the cases in which it was performed after attempts at forceps delivery it had risen to 26 per cent. With the introduction of Caesarean section through the lower uterine segment and delivery of the placenta and cord through the cervix and vagina after closure of the uterine incision, as suggested by Munro Kerr, there is probably less risk of infection, and he has published a number of such cases safely delivered. It is too early to write dogmatically upon this, but this method does seem to give much greater safety from infection in "suspect" cases, and there is a growing appreciation of its value.

Another factor which renders these cases more liable to sepsis is that many of the women are admitted with lacerations of the cervix and vagina produced by attempts to deliver them with forceps, in many others the patient is so shocked by the previous manipulation that an abdominal section is quite out of the question.

In the majority of cases admitted after attempted delivery Caesarean section is out of the question, owing to death of or damage to the foetus, definite infection of the mother, shock, or severe lacerations of the cervix or vagina, and in the small remaining group of suspect cases where none of these definite contraindications appear there is a justifiable difference of opinion. Some operators, and a growing number, will operate through a lower uterine incision with delivery of placenta and membranes by the vagina, whilst others consider the risk of sepsis too great even by this method.

When the dangers of Caesarean section were overcome and the operation leaped into popularity it was expected that the number of craniotomies would reach a vanishing point, but this is far from being the case. In 1906 in St. Mary's Hospital, Manchester, the number of Caesarean sections was only four, whilst there were fifteen craniotomies, in 1925 the number of Caesarean sections had jumped to 132, but the craniotomies, instead of diminishing, had increased to thirty. Craniotomy, nowadays, is seldom performed except upon cases sent in after intervention, and these figures are a strong indictment upon one class of obstetrical practice.

Pubiotomy is another operation which may be employed in this type of case, and a few operators do employ it, but it has many disadvantages and has never become popular. The only type of case in which it is useful is one in which the pelvis has a degree of contraction which just prevents extraction of the head, but which will just allow the head to pass after it has been widened by the comparatively small amount obtained by the operation. If this amount is miscalculated there is great danger of severe laceration of the soft tissues.

Dr. Hendry has pointed out how most of these cases could have been avoided by detailed ante-natal care.

What we have now to consider are the main causes underlying this state of affairs and the best method of removing these causes. There is little doubt that apathy is the main reason—the general failure of both the profession and the laity to realize the risks of labour and that special knowledge is necessary for the skilful treatment of abnormal cases—and the crowding of obstetrical teaching into any part of the curriculum not already occupied by medicine and surgery. These faults are due as much to the apathy and ignorance of the lay public as to that of our profession, and it behoves us, in seeking a remedy, to stress the importance of the education of the laity.

In the minds of the laity labour is a natural function—if it ends successfully it is no credit to the doctor or the nurse if anything goes wrong then the attendants must be to blame. A practical outcome of this is the very small remuneration paid for attendance upon a maternity case. A doctor may attend a case for twenty-four or forty-eight hours, may be up one or two whole nights, may completely dislocate the whole work of his practice for some days, during which time he is worn out with anxiety for this

patient and the others he is neglecting and yet when all is over he receives in remuneration less than he would for removing tonsils or any minor operation, and in credit very little beyond what is due to his pleasant and sympathetic manner, as he has only been observing a normal function.

If anything abnormal arises he is expected to recognize it and treat it, the fact that he is a qualified medical man makes him, in the opinion of most of the laity, an expert obstetrician capable of tackling any obstetrical problem. If, in his modesty, he recognizes that the abnormality requires someone more experienced than himself, he feels this means a loss of prestige in the eyes of the patient and her friends and that he will be blamed for the extra expense incurred.

Until the general public realizes the responsibility entailed by every maternity case, no matter how straightforward, and the anxiety, dislocation of work, and broken rest which many cases involve, and until the general public realizes the skill and patience necessary for the conduct of the simplest labour—increase a hundredfold in cases of delay and difficulty—and is prepared to pay fees commensurate with the time and anxiety involved, so long will the temptation remain to hasten delivery by every available means.

This subject of fees applies to the nursing as well as to the medical profession, and it is most noticeable at examinations of the Central Midwives Board to find that all the better class of candidates are taking this diploma merely to help them to secure senior appointments and with no intention of practising midwifery.

The fault, however, does not lie entirely with the lay public, we as a profession must take a considerable share of the blame for the state of affairs which can allow such a series of cases to be brought forward. In the past midwifery has not been taken sufficiently seriously. Until 1888 it was not compulsory for a student to attend any cases of labour before qualifying, and even now it is necessary for him to spend only one month in a maternity hospital, whereas he must spend six months dressing in a surgical ward. After that date he had to be signed up for twelve and later for twenty cases, but it was possible to attend these without seeing any abnormality, and so he entered practice without any realization, other than theory, of the serious difficulties to be encountered, and, never having seen obstetrical operations performed, could not realize that a trained obstetrician would perform these operations more skilfully and with much less risk to mother and child than he could do in his own bungling way.

When we remember the haste with which we completed our twenty cases, the surroundings in which many had to reside while attending these, the fact that many students never saw a member of the honorary staff of the hospital, or even an abnormality treated by a resident, can we wonder that midwifery was looked upon as a bore and every case of labour as a nuisance which must be terminated as quickly as possible, and especially that the student should soon consider himself, as did his neighbours, as capable of conducting a complicated case as any specialist? The month's residence in hospital which is now compulsory has improved this, and it must be impossible for any student to spend this time in hospital without seeing a considerable number of complications treated by the members of the medical staff, but this time should be extended.

It is the proud boast of many men in practice that they have attended a certain number of thousands of labour cases and carried out all obstetrical operations, and therefore know as much as, or more than, any young consultant, though they overlook the fact that the consultant will probably have more experience of difficult cases concentrated into one year of hospital life than the practitioner can acquire in a lifetime, and moreover, learns to perform these operations under men already skilled in performing them.

It is a great pity that there is this feeling of antagonism to young consulting obstetricians, it does not apply to young surgeons or physicians or even to young gynaecologists, and it would be all to the advantage of a young

practitioner if he would call to his aid in midwifery difficulties a highly trained specialist who would show him how best to deal with the problem.

The fact that the young graduate is not a specialist in obstetrics and has not had experience in performing all obstetrical operations is often laid as a charge against the competence of his obstetric teachers. In the past there was perhaps some truth in this, though the chief fault lay in the regulations which allowed the student to attend a certain number of cases without being in a maternity hospital and without coming in contact with the teachers, but that is altered now, and during the month's residence there is every opportunity to hold classes, and although the irregularity of the admission of abnormal cases makes it impossible for the senior members of the staff to demonstrate the operative treatment in all cases, they can hold classes on the most important clinical subjects.

There has been a great revival in clinical teaching in the last few years, and every large teaching maternity hospital endeavours to make the best use of its opportunities, and in the month at their disposal give each series of students a sound clinical foundation for their future work, but it must be emphasized that there are limits beyond which they cannot go, and even with more time at their disposal it is impossible to make every student a specialist, if for no other reason than that the number of abnormal cases admitted even to the largest maternity hospital would not provide sufficient material. If a graduate wishes to have special experience in operative obstetrical work he must be prepared to spend some time as a house-surgeon in a maternity hospital.

In teaching clinical obstetrics special emphasis must be laid upon certain sections of the work, and if this is done the graduate of the future will be turned out capable of taking charge of normal cases, of recognizing abnormalities, and of treating the minor ones, and with a sound clinical foundation upon which to build with future experience. The following four points are of importance and require special emphasis.

1 Ante-natal Work

More and more emphasis is now laid upon the importance of the constant supervision of the pregnant woman. If this is universally done the great majority of the cases of eclampsia will be eliminated, defects in the measurement of the pelvis will be detected and appropriate treatment undertaken, and defects in the position of the child recognized and rectified. If this had been universally carried out in these three cities one large group of cases—the contracted pelvis—would have been eliminated from our tables and these women saved much mutilation and have acquired living children.

It is almost unbelievable how little attention is given to this in some quarters. One of the chief reasons is the modern tendency of women of the working class to engage a midwife, who calls in a doctor only in cases of difficulty. This is the wrong way round, every pregnant woman should be under the care of a qualified medical practitioner, and if no abnormality is found the actual labour could be attended by a midwife. Even with this defect it is difficult to imagine the mentality of a man who applied forceps to a patient with a history of four previous confinements, two of which ended in craniotomy and two in Caesarean section, and yet such a case occurs in the list from my hospital.

Even the health authorities in many centres hardly realize the special training required for the work, and appoint to the charge of their ante-natal clinics young newly qualified practitioners without previous experience in this work, and with little or no chance of acquiring it in the future, as they will not see any of these cases in labour and so learn from their own mistakes.

2 Antisepsis

It is impossible to overstress the importance of this, and it is impossible to shut one's eyes to the fact that with many practitioners this is of a most sketchy variety. I cannot help thinking that the almost universal use of coal-tar derivatives has had a bad effect. Used in sufficient

strength to be really antiseptic they are hard upon the hands, and so the tendency is to use them in insufficient strength.

If thorough antisepsis had been carried out there is no reason why these unsuccessful forceps cases should show a higher morbidity than other forceps cases in the hospital, but the figures quoted by Dr. Miller show these to have a much higher incidence than those treated primarily at the hospital.

3 First Stage of Labour

In a straightforward case this is undoubtedly the most trying to all concerned. The patient and her friends naturally desire its termination, and use what influence they can upon the doctor to terminate it. This, no doubt, accounts for the large number of cases in our list in which forceps were applied before the cervix was dilated, the majority of which delivered themselves after time had been given in hospital for the cervix to dilate. These cases admitted after forceps failure possessed stout cervixes which would not tear, but for each of these there must have been a large number in which delivery was accomplished by tearing through the cervix.

It is impossible for any practitioner to resist the importunities of the patient and her friends unless he has a good clinical experience of this stage of labour, and can assure them that all will be well with a little patience. The old method of attending a certain number of cases gave no experience in this stage, but it is being emphasized more and more to-day. In my own opinion—and I think all teachers will agree with me—a student learns much more from attendance upon one case from the earliest part of the first stage to the completion of labour than upon a large number observed only at the end of the second stage.

4 Importance of making a Definite Diagnosis before applying High Forceps

Forceps applied when the head is on the perineum often relieves the patient of much suffering, and with many practitioners this is frequently done with great benefit, but forceps applied while the head is at the brim should be a rare operation, much rarer than it was in the past, as Caesarean section has removed a large group which otherwise would require this operation, and it should be performed much less frequently than it is.

A rule should be made never to apply forceps with the head at the brim merely because of delay in labour, a definite diagnosis of the cause of delay should be made, and if the practitioner cannot make this diagnosis he should call in the help of one with more experience.

Occipito-posterior positions are very difficult to diagnose, and those with the greatest experience will acknowledge that they frequently fail to make this diagnosis until the cervix is sufficiently dilated to allow a hand to be passed through the external os and the ear of the child felt. This is an infallible method, and if only it had been carried out before applying forceps this very large group in our series would have been eliminated. The treatment of occipito-posterior cases is simple, as Dr. Miller has pointed out, if only they are recognized, but to apply forceps at the brim with the head in that position is to court disaster.

If only the rule of making a definite diagnosis before applying forceps at the brim had been carried out practically all the cases in our series would have been eliminated, and many other women, in whom delivery was accomplished, would have been saved from mutilation. With this rule faithfully observed forceps would not have been applied before full dilatation of the cervix, while cases with contracted pelvis and occipito-posterior positions would have been recognized and easily treated.

This is a subject which behoves us, as a profession, to study carefully, it has been brought forward in no spirit of carping criticism, but in the hope that a free discussion between so many of us interested in obstetrical work, but looking at it from many angles, will result in practical advancement.

RECENT ADVANCES IN THE DIAGNOSIS AND TREATMENT OF HUMAN HELMINTHIASIS *

BY

CLAYTON LANE, M D LOND,
Lieutenant-Colonel I M S (ret.)

ADVANCE is not necessarily synonymous with progress. Recent work in these directions has concerned itself largely with ankylostomiasis.

DIAGNOSIS

Recent advances in diagnosis have been *direct*, the recognition of a parasite, or of part of it, just as it is recovered from man, *subdirect*, implying its deliberate development to some further stage before diagnosis is attempted, *indirect*, the searching for evidence of man's reaction to the parasite, or of damage which it has inflicted on him.

DIRECT DIAGNOSIS

Animals being nearly always classified on their adult structure, accurate identification of an adult helminth, usually macroscopic, involves accurate diagnosis. But the stage ordinarily available for this purpose is an immature one, and immature forms may be closely similar over large zoological groups. Moreover, too small a quantity of material may be examined. An accurate diagnosis by recognition of eggs in faeces can be made only if a female intestinal worm have a normal oviposition rate, if this rate be known, and if there be examined a fair faecal sample of sufficient size to display eggs with certainty when a single female is normally ovipositing. The normal oviposition rate can be ascertained by accurate determination of the number of eggs in the faeces and of the number of worms in the bowel contents. So reliable has worm detection been held that it has unhesitatingly been used to check—and to condemn—the accuracy of microscopic diagnosis by detection of eggs. The microscope has cruelly retaliated by finding fertile eggs when search of the bowel contents has revealed no male worms. The worm content of the bowel is no easy matter to determine, nor is the ovum content of the faeces.

Egg counts have been used since 1885 for determining the oviposition rate of hookworms, and recently for determining the accuracy of various counting and concentrative diagnostic techniques and for establishing the degree of infection of a community. These uses are correlated yet distinct, and merit further consideration.

The Accuracy of Concentrative Diagnostic Techniques

These techniques, after complete disintegration of the faecal conglomerate into its constituent particles, lead eggs in one direction and faecal matter proper in another. Comminution through overlying by faecal particles being largely removed, many eggs can be collected in a small area for ready examination. The efficiency of any such concentrative technique can be settled only by the use of controls which determine the number of eggs which the amount of faeces it uses contains and the number which it collects for diagnosis. Many concentrative techniques have been devised and advocated, almost none have been controlled. The first attempt to control a diagnostic technique by egg counts was my own ten years ago (1918). It was also, apparently, the first deliberately instituted egg-counting method used in determining the degree of infection of members of a community. Another egg-counting control was described by myself in December, 1922, a third by Stoll in January, 1923, designated by him "the egg-counting method," three others by myself (1924), and one by the Coldwells (1926). In testing the relative value of these I reasoned that the technique which, measured by egg counts, habitually delivered the largest number of eggs from the same evicted material must be the most nearly accurate, and I showed that that position is held by a peculiar modification of the concentrative technique named direct centrifugal flotation† (DCF), the

modification by which it is "pushed to finality." No criticism has shaken that proof.

Using carefully controlled conditions, DCF pushed to finality has given me higher, more regular, and therefore more accurate counts than any other, and Stoll's technique the most erratic and undependable counts of all. The accuracy of DCF pushed to finality has been questioned by Stoll and Hausheer and by Soper. I conclude from careful study of the papers that disintegration of the faeces was inadequate, the former, for instance, rejected pontifically (without evidence offered) the comminutor advised, an instrument which ovum counts have shown to be the most accurate at our present disposal, and obtained that type of ovum collection which is produced by inadequate disintegration of faeces. Any technique can be discredited by failure to disintegrate faeces completely. For the accuracy of Stoll's technique its author has offered no evidence, but maintains, against his own work, that it is accurate to within 10 per cent. It has been declared inaccurate by Hill, Maplestone, Sweet, Davis, Gordon, Chandler, and Soper—that is, by all who have reported on it independently, with the one exception contained in the report of Barnes and Russell from the Straits Settlements. They held it accurate for the inadequate reason that from it they obtained even results, yet their assistants could not do so. Evidence shows, then, conclusively that DCF pushed to finality is the most nearly accurate counting or control method of which we have knowledge. It is, on present findings, obligatory where exact knowledge is required. In the grading of concentrative techniques such exact knowledge is completely essential.

The same investigation has shown that every concentrative technique has its limit of effective concentration, that if it be used in too great concentration it becomes inefficient, first relatively, then absolutely. With due regard to this reservation and to the proper disintegration of the faeces, DCF in the first adequate spin or centrifuging and with rapid lift, using faeces from a lightly infected case not on a milk diet, has delivered over a considerable series of cases 80 per cent of the ovum content as shown by the same method pushed to finality. The minima and maxima were 61 and 95.

The Oviposition Rate of Hookworms

The minimum ovum content normal for hookworms is the oviposition rate of the female hookworm expressed as the number of eggs present in a unit of faeces. I have not found that this number habitually drops below about 30 per cent when tested by DCF pushed to finality, and have concluded that this is the number produced by a single female in normal oviposition. The estimates of others, obtained by comparing egg counts with worm counts, are Lutz (1885) 42, Leichtenstern (1885) 47, Darling (1922) 22, Stoll (1923) 40. Now DCF uses 1 c.c. of faeces, and 1 c.c. of faeces contains 30 eggs if a single female be normally ovipositing. Used diagnostically, DCF will deliver of these normally 24 and perhaps 18. If these conditions are fulfilled and these facts are correct, only gross carelessness can avoid a certain diagnosis by DCF. The acceptance of a higher rate for ankylostomo infection may or may not prove correct. It is, I believe, based at present on undependable considerations.

The Degree of Infection of a Community

Knowledge on this point is usually required as a preliminary to a treatment campaign. To its individual ascertainment strong exception has been and is being expressed on the score of uncertainty and cost. Since DCF recognizes the presence of a single healthy female hookworm, the first objection fails. Expense consists largely of pay of personnel, which itself depends on the time taken to prepare and to examine specimens. The time of preparation for a single specimen, mainly taken up with that complete disintegration which is absolutely and fundamentally essential, varies comparatively little with different methods, but no concentrative technique, other than DCF, permits of mass methods, in it twelve specimens can be disintegrated and centrifuged as rapidly as one. The time of microscopic examination varies roughly with the area to be covered, in Willis's technique, so commonly employed, this

* Read in opening a discussion in the Section of Tropical Medicine of the Annual Meeting of the British Medical Association, Cardiff 1923.
† The spelling implies the floating principle applied to diagnosis.

extends to 1,250 sq mm (2 sq in.), in plain DCF it is 150 sq mm (1/2 sq in.), in DCF with herding movements* it is 10 sq mm. This small area can, in quite deliberate manner, be examined at the rate of sixty specimens an hour. Moreover, herding can be effected for twelve slides as rapidly as for one. Further, eggs in faeces covered with water and kept at a temperature not exceeding about 28° C (80° F) retain full capacity for floatation for several weeks. Accordingly a comfortable central laboratory (in which accurate and rapid work can be strictly exacted without hardship) can be fed from a wide collecting area, and reserves of specimens can be left for a time to accumulate until it is convenient to examine them. All this implies that a supervised laboratory party of four (in India two microscopists of the compounder class and two sweepers) supplied with a twelve-tube centrifuge, can report comfortably on a quarter of a million negative specimens a year, and on a greater number in proportion as the number of positives is greater than this. It seems to me, then, that no justification exists, moral or financial, for denying to "native" communities an individual mass diagnosis. That, at present, must be effected by DCF, seeing that it is not merely accurate, rapid, cheap, and reasonably fool-proof, but is the only technique to which mass methods are applicable. It marks the fulfilment of an aim which I set before myself over ten years ago, and have since then steadily pursued. Here at least advance and progress seem synonymous.

But if, in investigating the degree of infection of a community, individual diagnosis be not the aim and accuracy be not desired, any of the other counting techniques will suffice, as will an estimate of the numbers contained in the head of a first DCF preparation, or even the examination of a simple smear. The means should fit the end. I cannot picture Solomon trying either to extract a cataract with a shovel or to belield an elephant with a v. Graef knife.

If all eggs of a nematode species have about the same specific gravity all will float in a non-absorbed watery solution of sufficient heaviness, and addition to its specific gravity will not float more. Conversely, one concludes that, if further addition to the weight of a watery fluid does not float more eggs, all have been collected. DCF pushed to finality in a saturated solution of common salt (sp gr 1200) does not deliver more hookworm eggs than does the same process carried out in a solution with a specific gravity of 1150. It is reasonably concluded that with the latter solution DCF indicates the content accurately. The same apparently holds for trichostrongylus and enterobius eggs. To float all ascaris and trichuris eggs a specific gravity of 1300 is required. As a counting technique this has great practical disadvantages, yet the figures hitherto obtained show that, used diagnostically with a saturated common salt solution, the first spin displayed on the average 40 per cent of the ascaris and 25 per cent of the trichuris eggs indicated as present. The minimum ovum content of both species is probably such that, used thus, DCF will detect a single fertilized normally ovipositing female of either species. Chandler reports DCF as floating hymenolepis onchospheres, but the percentage of success is unknown. For nematode eggs, onchospheres of taenia, unfertile ascaris eggs, and strongyloides larvae all floatation methods are undependable.

For the collection of those ova which it floats DCF should be used selectively, employing a solution whose specific gravity is no higher than necessary. The usual practice of stating, both in original papers and in uncritical abstracts of them, that the local percentage of worm infections reaches a certain figure, without stating the diagnostic procedure used, is valueless. Such reports and abstracts do not register progress.

SUBDIRECT DIAGNOSIS

For hookworm infection this method has recently been allotted primary value. Faeces containing hookworm eggs are "cultured" and extracted in water. The principle, that of Looss, is effective only if larvae are infective in

stage and active in movement. Its details have been altered needlessly. Baermann's modification is convenient and well known, my own has the advantage of compactness in that several dozen cultures can be set or extracted simultaneously in a single incubator of ordinary size.

This method of diagnosis has constantly failed for two opposite reasons—the first that the worms (eggs or larvae) have died before extraction, the second that their activity has carried them out of the culture before its extraction. A hookworm larva is obligatorily aquatic, living normally within the water films which enclose particles of a moist soil. It passes from one particle of soil to another—readily if both lie within the same film, laboriously if the film has to be lifted until contact and fusion with another film are established. A larva may burst through the surface of a film and travel on, clothed with a minute and steadily lessening film of its own. If it does not enter another before its own is lost it must surely die.

To combat the diagnostic error introduced by larval death before extraction, our knowledge is at present insufficient. To circumvent the error induced by escape every culture must be surrounded by a water trap. Into this trap migrating larvae tumble, and out of it they rarely escape. Indirect diagnosis not only is uncertain, but has introduced a completely unnecessary risk for those who have used it. It has been employed in a series of well watered and untrapped soil samples to determine the duration of infection of the soil—that is, the longevity of hookworm larvae. Their disappearance from the sample may, however, be evidence, not of premature death, as is almost universally concluded, but, equally, of exuberant and vicious vitality.

For strongyloides infection culture with extraction or tracking in agar has been used successfully. Largo cultures are advised, but the method's efficiency is really unknown, seeing that no satisfactory controls have hitherto been devised. It is, then, questionable to what extent there has here been advance, conclusions should be drawn with caution.

In infection with *Schistosoma japonicum*, snbdirect diagnosis has a possible concentrative place. As Faust and Meleney point out, miracidia hatching out in clean water congregate in its upper few millimetres and, if melaniae have left a slime-track there, hover excitedly about that particular portion.

To sum up, apart possibly from infections elucidated by faecal examination, subdirect methods seem to offer little opening.

INDIRECT DIAGNOSIS

1 Evidences of Reaction to Helminthic Parasites

Eosinophilia in the blood was shown twenty-five years ago to be absent in the worst cases of hookworm infection. On the other hand, in Boycott's two deliberate infections it appeared about three weeks before eggs were found. Local eosinophilia in the tissues may be a marked feature of local infection. Local fibrosis may follow the local leucocytosis of which the local eosinophilia is an evidence, and of fibrosis onchocerca nodules are perhaps the most striking clinical evidence. Yet recent investigation has shown that these may commonly be undetectable when the corresponding microfilaria is present abundantly in the lymph of the lumbar region. In the same direction points Dyce Sharp's observation of a female onchocerca escaping from an ulcerated and non-nodular surface. A fibrous reaction seems no more a necessary part of the diagnostic picture of an onchocerca than of a loa infection.

Creeping Eruption.—Looss described this in connexion with penetration of the skin of his arm by a number of strongyloides and ancylostoma larvae. Kirby Smith was apparently the first to demonstrate a larval nematode in the epidermis in such cases—cases, that is, not due to fly larvae. Fülleborn has shown by serial sections that larvae of the dog mcinaria, applied to his own arm, produced tunnelling of the epidermis, the tunnels filling with lymph, breeding bacteria, and producing dermal inflammation. His observation suggests that, when creeping eruption is due to the larva of a nematode, that larva belongs to a species for which man is an unsuitable host. Failure to make the usual immediate entrance into the dermis is

* Herding is effected by to-and-fro and circular movements which collect ova about the centre of the hanging preparation obtained after D.C.F. with rapid lift.

explicable as abhorrence of the larvae for lymph with man's specific lymph character. The worms cannot, so to speak, bring themselves to enter as usual the dermis where that lymph is characteristic, but wander forlornly in the epidermis, where it is so disguised by excretions from epidermal cells and bacteria that it becomes, for those particular larvae, at least endurable.

Sensitization.—The principle of the Casoni reaction for the diagnosis of hydatid disease has recently been extended to other helminthic infections, particularly by Fülleborn. In strongyloides infection the "flames," consisting of masses of filariform larvae, are sterilized and dried. This vaccine, used within a year of production, is rubbed into the shallowest possible scratches in the skin, for the least bleeding is harmful. In a pronounced reaction urticarial swelling begins in a couple of minutes, reaches its full size of about 15 cm in diameter in about fifteen minutes, and begins to disappear in about an hour. The reaction appears to be constant in infections having a duration of eighteen months or more, and was present once in eleven cases where all other evidence suggested absence of infection. With this reaction Fülleborn correlates like lesions constantly appearing perianally in chronic strongyloides infection, and that in spite of meticulous care in cleanliness. These he attributes to natural development to the filariform stage of larvae in tiny particles of faeces retained in minute perianal creases and their penetration of the perianal skin. Such repeated auto-inoculation would explain the long duration of some of Fülleborn's cases, one extending to over twenty-four years. For ascariis infection Fülleborn makes his antigen from the body wall of *Ascaris lumbricoides*, recovered from the pig, after the cuticle has been rubbed off, while Ransom, Harrison, and Crouch use the body fluid of the worm. These last workers found four of twenty persons sensitive. None, apparently, had been or were infected, but their work had brought all four into contact with ascariis for five to twenty-five years. Sensitiveness to ascariis material seems to hold no necessary implication of infection. This reaction will have a practical diagnostic value only in so far as it is positive at least as frequently as is the appropriate direct examination.

Complement fixation.—Here the recent work of Hamilton Fairley is important. In echinococcus infection he finds that scolices must form the antigen. The most suitable material is scolix-containing fluid from pulmonary or hepatic hydatid cysts of the sheep. Examination of nearly 1,000 cases showed that a positive reaction was clear evidence of hydatid infection, but absence of reaction did not necessarily exclude this. Age is important. Of infected persons under 20 years of age about 40 per cent gave no reaction while of those over 60 years old all reacted. Failure is variously caused. Not all cysts contain scolices—that is, antigen. Not always is antigen absorbed, as appearance of complement fixation for the first time after rupture of a cyst shows. Very rarely is antiserum not formed. Fairley concludes on very strong grounds that persistence of this reaction for more than twelve months after removal of a cyst implies persistent latent infection. In schistosomiasis Fairley's antigen is again a larval form—the cercaria in the snail's liver. This reaction is not zoologically specific, since using livers of *Planorbis exilis* infected with cercariae of *S. indicus*, he has obtained effective reactions not only in infections by this parasite in goats and buffaloes, but by *S. indicus* in goats and by *S. haematobium* in man. Although a generic reaction it is sensitive and valuable, seeing that no effective direct concentration technique has been devised for the extraction of trematode eggs from faeces.

2. Appraising the Damage done by Infection

Stiles instituted two methods of approach to this problem.

(a) *In the same community infected were compared with the presumably uninfected.* He selected a group of school children containing individuals positive and negative to the smear and to all of them applied certain physical and mental tests. Speaking generally these were negative but those children infected with necator were lighter and shorter than those in whom the smear failed to detect infection. In Queensland Waito and Nelson, examining

about 11 square inches of smear, partly centrifuged concluded that they could demonstrate a retardation of mental development and of haemoglobin content corresponding to the degree of infection, and that the effect was cumulative. Gordon could find no connexion between helminthic infection and haemoglobin percentage, physique, general fitness, or mentality, except that an ankylostome infection of over 15,000 eggs per gram of faeces involved loss of energy.

Two drawbacks attend this method. First factors other than helminthic infection may be influencing the subgroups. Neglect, ill feeding, and inherited mental weakness may well be preponderatingly with the infected group. Secondly, the mode of diagnosis used has failed to differentiate the infected from the non-infected.

(b) *The same community was tested before and after treatment.* In an infected person the bodily state at any particular moment represents the balance between damage done and repair effected. This repair entails an unusual often continuous, call which depletes bodily reserves even if immediate compensatory hypertrophy occur since capacity for hypertrophy is always limited and has been encroached upon. This depletion of reserve must be measured if the damage done by an infection is to be appraised. Stiles's second group of tests noted the change in mortality, morbidity, and capacity for work which followed disinfection. Under Wise in British Guiana disinfection of those apparently in good health was followed by marked improvement in all these directions. Life became more comfortable, happier, healthier, longer. The same followed my own treatment of 20,000 infected persons in Darjeeling twelve years ago. This line of testing, dropped for some years, has happily just reappeared. For example, the *Transactions of the Royal Society of Tropical Medicine and Hygiene* (vol. xxi, No. 6 1928) contains two instances. The first by McKenzie (p. 461) records the gain in weight and working capacity following the disinfection of a gang of "healthy" hard-working negroes, the second, by Rose (p. 486) stresses the striking rapidity with which lepers, who had failed to respond to treatment, did so when they were rid of their hookworms.

Exact inquiry on these lines seems to have greater scientific possibilities than any other. It is more likely to deal with single factors and it investigates that side of the matter which calls out for clarification. Two requirements are essential. (1) the diagnostic technique used must detect at least the single female worm for which purpose D.C.F. is at present essential in hookworm infection, (2) there must be evidence that the tests used do actually detect disability present. When Smilie and Spencer state with emphasis and confidence that, on the basis of the Stoll technique and of the physical and mental tests which they have used, "very light hookworm infestations produce no measurable harm," and conclude that these children are merely carriers whom it would be unjustifiable to treat to disinfection, they assume, without evidence offered, unjustifiably, and as I believe incorrectly, that the tests they have arbitrarily selected are accurate and adequate. It is as useless to attempt to measure entamoebae with a foot rule, whether procured from Mr. Woolworth or from the Greenwich Observatory, as to record the hours of sunshine with the most delicate of barographs. There is no justification for the assumption that no individual harm is here measurable. That will be determined only when the two requirements just noted have been met. But whatever may be the final answer on this point the matter will not thereby be closed, for the harm a light infection does is not limited to its possessor, nor does his degree of infection constitute any measure of the risk which he is to the community. This will perhaps be startlingly clear from the conservative statement that given ideal conditions of extracorporeal development and of establishing contact with man a single pair of hookworms is mathematically capable of destroying the human race within a year. It must be, and is, these extracorporeal conditions which are all-important. It is almost true to say that the intensity of an individual's infection is largely entirely immaterial. What is vital is the fact of infection and his particular, and often peculiar, fancy in defaecation. Unless that be rigidly

controlled in a primitive community, and conceivably it cannot, hope must lie in exact individual diagnosis and in treatment to disinfection.

TREATMENT

The perfect anthelmintic, when we find it, will be, or will produce, a selective poison which in a single dose will kill all worms without injuring the host or risking his life. Pending the discovery of a drug with these properties, effective against even a single worm species, anthelmintic dosage must be so limited that the enthusiastic prescriber will not find himself killing man in order to kill his parasites. Since these parasites live in a fluid medium, it has been concluded that the greater the concentration of the drug in that medium the more helminthoidal will its action be. Hence has arisen the stereotyped routine for the expulsion of intestinal helminths—preliminary starvation and purgation to lessen the volume of the intestinal contents and to produce thereby the maximum perihelminthic concentration of a vermifugal drug, when this is administered in the largest dose safe for man, which must be less than its minimum lethal dose.

It is profitable to consider first the action of tartar emetic and emetine in the treatment of schistosomiasis. Recent work has firmly established their value. Their mode of action is illumined by Fairloy's work. He showed that, as compared with solution in water, solution in serum increased the cercaricidal action of these drugs more than a hundredfold, while in plain normal serum, in that from a bilharzia case, in water, or in normal saline solution, cercariae live thrivingly. Clearly parasitic death in these cases is not due to direct poisoning by the drug. Quinine acts similarly on cercariae, which parallels its mode of action on the malaria plasmodia. These drugs themselves are not parasiticidal, they must be changed into something else before they become so. Does the same hold good for intestinal anthelmintics? Apparently it may. I have not been able to consult originals, even in translations, but it is stated that santonin and its derivatives are excreted into the lower part of the intestine when the drug is administered subcutaneously or by mouth after occluding the intestine, and that Takagamo and Asada claim that santonin is not vermifugal, but after absorption it, by combination with bile and other substances, becomes so for certain intestinal worms. Accordingly certain anthelmintics are innocuous or nearly so, but poison worms indirectly.

Moreover, when a drug has to be altered by the body before it becomes vermifugal, an interval should elapse (in the case of santonin twelve hours) between its administration and the post-anthelmintic purge. For the use of this last, recent work has strengthened the triple reason: the man is well rid of such of the toxic drug as remains in his gut, of the toxins shed into his gut by dead worms, and of drunken but living worms (a condition marked with certain anthelmintics) which should be swept away before they recover their unpleasant instinct for attachment.

Apart from schistosomes, hookworms have attracted the greatest modicative interest of recent years. Thymol in 60-grain dosage has served well. More recently other drugs have been extensively used—for example, oil of chenopodium and its active principle ascaridole. Schüffner's advocated dosage for the oil was 12 c cm, which is 48 drops delivered by the international drop-counter, not 48 minims. The use of this last and erroneous dosage has led to a number of deaths, the lower seems to be safe when the ascaridole content lies, as it usually does, between 50 and 70 per cent. In oils with a high ascaridole content, such as that issued by Burroughs Wellcome and Co (90 per cent), the dosage should be 0.8 c cm. The usual dose of ascaridole is 0.5 c cm.

Carbon Tetrachloride

The most recently and enthusiastically advocated drug for the treatment of ankylostomiasis was introduced to medicine by that distinguished veterinarian Maurice C. Hall (who has done so much for the diagnosis and treatment of helminthic infection) in an advocated dose of 3 c cm equally for man and dog, the dosage being apparently

irrespective of weight even between dog and dog. The drug is held to have no minimum lethal dose, and of it Lamson and Wing write "In the very extensive use of carbon tetrachloride in the treatment of hookworm disease, a few cases in each million have died." What are the facts? By shutting one eye or the other they can be made to suit any fancy. On the one side are such instances as Khalil's, with 150,000 cases treated with a partly redistilled drug, and one reported death, and he a poor creature—surely here, at last, is the perfect anthelmintic, which will destroy only "a few cases in each million," and those the ones we best can spare, Bishop's in Trinidad with 25,000 cases and no reported death, Lambort's 40,000 cases with no deaths, and yet three deaths in the next 8,000, Kohrer and Oondendal's, using 5 c cm with 1.5 c cm of oil of chenopodium, with no deaths in the first 9,000 and five in the last 6,000. On the other side lie Straub's two deaths in 1,400, one after a dose of 2 c cm, and three deaths in hospital patients after doses of 1½, 2, and 2 c cm, Kouwenar's four deaths in 6,000, none getting more than 3 c cm and the drug passing chemical tests of purity, Neave Kingsbury's one in 143 with a dose of 5 c cm, Phelps and Win's with two deaths one in an adult taking 3 c cm, the drug being pure, Bais's with three deaths. It is well to read the results with both eyes.

Are such deaths entirely unforeseeable? Carbon tetrachloride produces fatty degeneration of the liver, and sometimes at least of kidneys and adrenals. In the former the change may be intense, and is ordinarily followed by phenomenally rapid regeneration. In single doses there may be produced a striking derangement of liver function, with increased bile pigment in the blood, reduced tolerance to leucine, a drop in the blood fibrin with production of haemorrhages, and a lowering of the phenoltetrachlorophthalic test for liver function. Yet if the drug be persisted in so that it actually produces "tremendous liver lesions of necrosis, scar tissue formation, and all the signs of an early cirrhosis of the liver," dogs so affected "give normal values for all these liver function tests." It is held that intoxication can probably be prevented by (a) avoiding administration of the drug without preliminary treatment for ascariasis, (b) refusing treatment to alcoholics, (c) having patients avoid alcohol and food before and after treatment, (d) ensuring an adequate calcium reserve. It may be said in comment that (a) in Neave Kingsbury's case this was effected and death followed, while the proposal renders absolutely obligatory microscopic examination of the stool before giving the drug, (b) alcoholics are little prone to announce the fact, (c) Davis has shown that a diet rich in carbohydrates lessens liver damage, (d) we are left wondering how attention to calcium deficiency can be effected on a mass scale. In other words, the recommendations do not enable the hygienist to foresee these tragedies. A dose of 1.5 c cm may kill and is less efficient than the older anthelmintics. I know, moreover, that all deaths from the drug are not being reported, and that such unreported fatalities have wrecked at least two hookworm campaigns. I believe that the general adoption of the drug is retrogressive, in that it obstructs investigation directed to the discovery of something far more nearly approaching the ideal anthelmintic than any we now possess.

The tests by which anti-ankylostome drugs have in the past been appraised are unsatisfactory. The work requires repetition, using as a basis the enumeration, by accurate means, of the number of eggs present in a unit of faeces before and after treatment. Recent progress in diagnosis admits, at last, of this being effected with confidence of success.

Mass Treatment and Herd Treatment

Finally, mention must be made of treatment of hookworm infection on an extensive scale. Of this there are two conceptions, surely morally incompatible. In the one, after a preliminary investigation of relatively few persons, to determine whether the community in question has a "sufficient" degree of infection, all are "persuaded" to accept treatment by a lethal drug without individual diagnosis. Euphemistically misnamed "mass treatment," this is, in fact, the drenching method which the veterinarian

applies to an infected herd of cattle. It is "herd treatment." I quote once more words by Major Church:

"To the native races," as Sir Frederick Lugard has said, "civilization must mean something more than the methods of the development syndicate or the assiduous cultivation of new wants."

The pursuit of wealth, if it is accompanied by the careless exploitation of native races, is neither an honourable nor in the long run a profitable policy for the representatives of a great nation.

Disinfested labour is more profitable labour, and it is easier to treat a whole heavily infected community herd fashion, at the risk of a few deaths in uninfected persons, than to determine who are infected and to treat them only.

The second and antithetic usage is an expression of the belief that every individual is entitled to an individual diagnosis of infection before he is treated with a possibly lethal drug. It is based on conviction of the extreme value of mass treatment, even to complete disinfestation, but admits of no justification in morality, science, or expediency for the infliction of herd treatment on backward races. Those advocating this second usage can now ask, "What possible justification is there for the herd treatment of hookworm infection when mass diagnosis has become so exact, and can be carried out at the rate of a quarter of a million specimens a year for every four persons employed in the actual preparation and examination of specimens?" Surely the answer is "None." We are further advised to adopt for herd treatment the use of a drug which has "no lethal dose" yet kills unforeseen in a smaller dose than that which is in habitual use in herd treatment. At the same time we are warned that the drug should be avoided in certain conditions whose presence, in the very nature of things, herd treatment precludes our discovering. If in these circumstances we elect to use herd treatment we shall, I am satisfied, not merely have disregarded our individual professional obligation to those we treat, but will have set our feet deliberately on a path which, for us at the present time, will be devoid alike of reason and humanity.

USE OF SUBCUTANEOUS INJECTIONS OF OXYGEN

BY

T S KIRK, M.B., B.Ch.,

SURGEON TO THE ROYAL VICTORIA HOSPITAL, BELFAST, AND THE BELFAST CHILDREN'S HOSPITAL.

EARLY in January of this year Dr Murphy of Lisburn told me that, as a last resource, he had treated one of his dogs, suffering from double pneumonia following distemper, with a subcutaneous injection of oxygen, and that this was followed by a rapid and dramatic recovery. This method of treating pneumonia in dogs was introduced and has been advocated for some time by Colonel Ryan, F.R.C.V.S., Cork. He treats such cases from the very start in this way and does not wait till the animal is seriously ill. I related this case to one of my colleagues, Dr Rowland Hill, showed him how to give the oxygen, and he has had at least one wonderful recovery, which he has published.

On February 4th of this year Dr Boyd Campbell asked me to give oxygen to a man in his ward. It was the ninth day of an attack of double pneumonia in a man aged 45. When I saw him both lungs were completely involved and his blood pressure had fallen. He appeared to be moribund. He was given a large dose of oxygen at 12 noon, and he died at 4 p.m. At 8.45 p.m. on the same day Professor Symmers performed a *post mortem* examination that was rather interesting. There was absolutely no rigor mortis, the blood that issued from the anterior skin incision was bright arterial blood, the muscles were a brilliant red, the parietal pleura was also bright red, and the blood in the inferior vena cava was a distinct blue colour, not at all black and tarry. The lungs were to a great extent in the state of grey hepatization and there was not a half-inch of healthy lung.

Since then several cases of acute lobar pneumonia have been treated with subcutaneous injections of oxygen immediately on admission to hospital, and their charts show uniformly good results. The crisis comes on very rapidly. A case of pneumonia complicating glossitis, a post-anæsthetic pneumonia, and a case in a man with a bad fracture of the pelvis have all done well.

These results, taken in conjunction with Dr Cannon's recent work, as published in the *British Medical Journal* of April 21st, on the inhalation of warmed oxygen as an early method of treating acute pneumonia, are very interesting and suggestive. Dr Cannon claims that pneumococci give off oxygen and when the gas is sufficiently concentrated in the tissues the micro-organisms die.

If oxygen—say about 150 ccm—is injected subcutaneously into a rabbit and a few minutes later blood is drawn from a vein of its ear, the blood will be found to be arterial in character, and when shaken up with air its colour cannot be heightened. Also such a large dose does not produce any bad symptoms, such as apnoea. There is no doubt that oxygen is rapidly absorbed.

In pneumonia there are two things wrong with the patient—a general toxæmia and the local changes in the lung. Usually the toxæmia is the cause of death, and the oxygen seems to do good by neutralizing the effects of the toxæmia as well as possibly by its action on the micro-organisms. Toxæmia kills by producing anoxæmia with reduction of the alkalinity of the blood, and the clinical condition of acidosis is produced. The acids in the urine, and in bad cases the glycosuria, indicate this state. The kidneys and liver, the organs apparently responsible for maintaining the proper alkalinity of the blood, may both be upset. It is possible, therefore, that oxygen given subcutaneously acts, as Dr Cannon thinks, by helping to kill the pneumococcus and at the same time counteracts the toxæmia.

Given subcutaneously oxygen certainly does not produce any lung trouble or aggravate any existing lung trouble, as it may when inhaled, even if heated, and although I have given it in at least two hundred cases, not a single local or general bad effect has been seen, so that it may be considered a perfectly safe procedure.

Subcutaneous injections of oxygen, besides being of great use in cases of pneumonia, are of value in all cases of anoxæmia, and these are numerous and serious.

Chloroform or post-anæsthetic sickness is due to acidosis, and all my operation cases in the Royal Victoria Hospital before leaving the table are given a dose of oxygen, with the result that sickness is much diminished, since January only one case out of two hundred has developed any post-anæsthetic pneumonia.

A striking effect of subcutaneous oxygen is seen in connexion with extensive burns and scalds of the body. I have long been interested in these cases at the Children's Hospital, and have tried to solve the problem of the rise of temperature about the third day and the subsequent fatal result. For years I believed this toxæmia was due to microbic infection, but after trying all the known means to combat such infection, and not meeting with any success, I gave up that theory. Lately I found that scalds and burns that are going to do badly develop, before any symptoms are noticed, a severe acidosis, and apparently the toxæmia is due, not to a bacterial infection, but to the breaking down of the damaged tissue—that is, it is due to histamine poisoning, or to something akin to it. Later on, undoubtedly, microbes may cause complications.

During the last two months all the cases of burns and scalds of the trunk admitted to my beds have been treated with oxygen, and only one patient has died, but this case was not admitted till the third day, when the temperature was raised, the pulse rapid, and acidosis well established. Three similar cases were admitted a few hours after the accident, were given oxygen at once, and all did well, at most their urine showed a slight and temporary acidosis. The amount of oxygen given was largely determined by the amount of acid in the urine.

An interesting point in connexion with anoxæmia is that symptoms do not appear till late, and once they appear the patient goes downhill very rapidly—almost as if he had fallen over a precipice. So that in treating anoxæmia,

or conditions giving rise to it, oxygen must be given early, before the patient becomes obviously very ill

A girl in my ward for some weeks had small boils in various parts of her body, then she developed acute peritonitis of the right radius—all due to a staphylococcal infection. When admitted her urine was very acid and contained sugar—it reduced Fehling's solution with the greatest ease. She was given 200 c.c.m. of oxygen and in twenty-four hours her urine contained only a trace of sugar. She had another 200 c.c.m. of oxygen, and next day her urine was free from sugar. During that time no incisions had been made in her skin.

The apparatus needed for giving subcutaneous oxygen consists of the gas cylinder, a coarse piece of rubber tubing attached to the valve, and this coarse piece connected by a joint of glass tubing with a finer piece of rubber drainage tubing, to the end of which is attached the needle of a serum syringe. There is no need to heat or filter the

CHART 1.—Acute lobar pneumonia, the right lower lobe extensively involved, the left lower lobe to a less degree. The oxygen was given on the third day of the disease.

gas. A convenient place to give the injection is below and outside the nipple or breast.

At first I measured the amount injected by means of two graduated bottles, one of which contained water. Such an apparatus is a nuisance, and is not required. I found that if sufficient gas is admitted under the skin so as to inflate an area equal in size to the palms of two hands, the amount given is roughly equal to 200 c.c.m. Much larger amounts can be safely given.

The time taken for the oxygen to be absorbed seems to vary according to the patient's need. It seems well in bad cases to give at least 400 c.c.m. at first and then see the patient in six hours, repeating the dose if most has been absorbed. A large dose of oxygen can be given as easily and quickly as a dose of serum, and it is less painful.

CHART 2.—Acute lobar pneumonia, left lower lobe. The oxygen was given on the fifth day of the disease.

Since the early days of haematology, when Ehrlich's work became known, attention has been focused on the various white cells of the blood, and the red cells, though far more numerous, have not been talked about much in connexion with acute and chronic infections. Perhaps they have been unfairly neglected. By dosing our patients with oxygen in this safe and easy way we can give the red cells a chance to show what they can do.

I have felt impelled to write this note on account of the uniformly good results seen in pneumonia and in burns and scalds on account of the simplicity of the method, and because I believe that the giving of oxygen is of benefit in many conditions. It is interesting to remember

that drugs such as alkalis, potassium chlorate, and potassium permanganate, all of which can help oxygenation, have long been popular in the treatment of acute and chronic toxæmias.

The accompanying temperature charts are typical of cases of acute pneumonia treated with subcutaneous oxygen.

POST-MORTEM FINDINGS IN A CASE OF RENAL DWARFISM

BY

H. A. COOKSON, M.B., F.R.C.S.E.D., D.P.H. CANAD.,
PATHOLOGIST TO THE ROYAL INFIRMARY, SUNDERLAND, AND TO THE
CHILDREN'S HOSPITAL, SUNDERLAND.

THE case here recorded appears to be of interest because of the absence of bone deformity in a girl presenting the other features of renal dwarfism.

Clinical Notes, May 1st, 1928.

The patient was a girl aged 16 years. The history obtained stated that six months previously she had an attack of pain in

FIG. 1.—Kidney, weight 21 grams (normal weight 140 grams).

the abdomen with vomiting and diarrhoea. She went to an institution and returned benefited. She remained well until three or four weeks ago when she suffered from abdominal pain and vomiting, and mentally was rather dull.

When admitted to the Royal Infirmary, Sunderland, on May 1st, the child looked drowsy and complained of abdominal pain. She was seen to be markedly undeveloped, looking between 11 and 12 years of age. The abdomen was rather

FIG. 2.—Kidney laid open. Weight 21 grams.

tumid. The heart showed no abnormality. The urine had a specific gravity of 1010, neutral reaction, albumin present, no blood, pus, or sugar. An endocrine defect was suspected. An x-ray report of the region of the pituitary fossa showed no enlargement of the sella turcica. The Wassermann reaction was negative. The blood count showed haemoglobin 45 per cent, colour index 1.02, red blood cells 2,200,000 per c.mm., white blood cells 9,600 per c.mm. Differential white cell count: polymorphonuclears 81 per cent, lymphocytes 18 per cent, no eosinophils or basophils, large mononuclears 1 per cent.

The patient gradually became comatose and died on June 3rd, apparently of uræmia.

Post mortem Examination

The general appearance suggested that of a child of 11 years of age. The body was well nourished and plump. No deformity of the limbs was noted. There was a bald patch, apparently alopecia areata, on the back of the head.

FIG 3

volutions. No tubercles were seen. The pituitary gland appeared normal.

The kidneys specially described (see Figs 1 and 2). These were very small. The surfaces were granular and the capsules stripped freely. A small cyst was present in the right kidney. The cortical area was greatly diminished. On section (see

FIG 4

Chest—Both lungs showed old chronic tuberculosis and tuberculous broncho pneumonia. The thymus was not persistent, and there was no increase or decrease in the size of the thyroid gland. The heart presented no peculiarity. The large vessels showed no degenerative changes.

Abdomen—Tuberculous mesenteric glands. The spleen and liver presented no abnormality. The uterus and ovaries were very small and undeveloped. The intestine showed no abnormality.

The brain showed some oedema and flattening of the con

dition was that of a progressive interstitial nephritis. During life an endocrine defect was suspected in the child and it was only at the *post mortem* examination that the condition of the kidneys was fully appreciated.

I am indebted to Dr R. Mair, assistant physician to the Royal Infirmary, Sunderland, whose case this was, for the clinical notes

associated with outbreaks of chicken-pox, as is shown in the accompanying table. This would suggest a common origin.

HERPES AND VARICELLA.

BY

N. GRAHAM HILL, M.C., M.B., B.S.

TOWARDS the end of last century von Bokay noted the occurrence of herpes zoster and varicella in the same households at the same time. Since there is a marked similarity of the skin lesions in the two conditions, he suggested that there might be a common cause for the two diseases, or, to put it in other words, the two conditions might be different manifestations of the same disease. During the last thirty-five years many papers have been published referring to outbreaks of varicella which have appeared to owe their origin to contact with cases of herpes zoster. The relationship of the two diseases has frequently been discussed, but no definite decision has yet been reached.

Le Fèvre, working among families living in isolated farmsteads in South Africa, made out a strong case on clinical evidence for the common origin of herpes zoster and chicken-pox, and Netter observed over a hundred cases, mostly French, in which herpes appeared to have given rise to varicella or varicella to herpes. On the other hand, chicken-pox was made a notifiable disease in Burton-on-Trent between November, 1922, and December, 1924, and the medical officer of health, Dr Cowie, or his assistant investigated every one of the 813 cases reported in 559 families. In only nine—that is, 1.6 per cent. of cases—was there a history of recent herpes in the family.

In Queen Mary's Hospital for Children, Carshalton, twenty-nine cases of herpes zoster have occurred among the patients and staff during the last two years. In spite of the fact that all cases of herpes and chicken-pox are isolated, eight of the herpes cases seem to be very closely

of the conditions. But against this finding we must place the fact that an attack of varicella does not confer any immunity against herpes zoster, seven of the twenty-nine patients gave definite histories of having had chicken-pox, and scars on the skin supported these statements. In not a single case have I seen, or obtained histories of, a second attack of either chicken-pox or herpes zoster, and I have not observed herpes and varicella rashes out together on the same patient, although many such cases have been recorded.

Conclusion

A case of herpes zoster may give rise to an outbreak of varicella, but a previous attack of varicella affords no protection against a subsequent attack of herpes zoster.

NINETY-SIXTH ANNUAL MEETING

OF THE

British Medical Association.

Held at Cardiff, July, 1928

THE SECTIONS

SUMMARY OF PROCEEDINGS

ARRANGEMENTS have been made to publish, during the next few months, full reports of the opening papers communicated to the Scientific Sections of the Annual Meeting at Cardiff. The summaries printed below and those which will appear in subsequent weeks are intended to give members who were not present a general view of each day's proceedings.

SECTION OF MEDICINE

Wednesday, July 25th

DISEASES OF THE CORONARY ARTERIES

SIR THOMAS LEWIS, President of the Section, who took the chair at the opening session of this Section, said that the generalization associating a man's age with his arteries should be limited more particularly to the cerebral and coronary vessels. The discussion about to be opened was timely in view of the recent growth in knowledge about this subject, and it might be recalled that rather over a century ago a small group of men in the counties bordering Wales had contributed materially to the little that was then known.

Dr G. A. ALLAN, in opening the discussion, said that disease of the coronary arteries had been recognized for a considerable time, and its association with angina pectoris had been widely accepted. In recent years prominence had been given to certain anginoid symptoms which had been found associated with coronary blockage, usually thrombosis. In this country the papers by McNeo and by Lindsay Steven had made a careful analysis of the literature as far back as 1887. Coincident with this increased attention to the clinical aspect important anatomical investigations had been made by Gross and his collaborators, in addition to making an accurate survey of the part of the heart supplied by each coronary artery he had also shown that the heart was perhaps the richest organ in the body as regards capillary and pre-capillary anastomoses between branches of the same artery as well as between branches of both arteries, and that as age advanced there were anastomoses between the vessels in the epicardial fat and adjacent parts and the coronary arteries. The morbid processes affecting the coronary arteries might be classified into four clearly defined conditions: (1) Atheroma, the commonest primary lesion, was a patchy disease first affecting the deeper layers of the intima with degeneration of

the deeper parts, proliferation of the fibrous elements, and encroachment on the lumen of the vessel. It was quite irregular in its distribution through the body, and might be well marked in the coronary vessels when there was no indication of it in the accessible arteries. (2) Arterio-sclerosis, a diffuse process characterized by thickening of media and intima, probably beginning as a hyperplasia in the media, it was much more uniform in its distribution than atheroma. (3) Syphilis was comparatively rare in the coronary vessels in spite of the fact that aortic syphilis was one of the commonest visceral manifestations of the disease. (4) Calcification was most frequently found superimposed on either atheroma or arterio-sclerosis, but it might occur as a primary medial degeneration, and its association with atheroma was a potent factor in diminishing the lumen of the vessel. To obtain some idea of the relative frequency of these lesions he had examined the figures collected from 1,000 consecutive autopsies in the Western Infirmary, Glasgow. In these there were 371 cases in which naked-eye lesions had been noted, the lesions were—

Atheroma	80.6 per cent	with fibrosis in	51.2 per cent
Arterio-sclerosis	45.3	"	54.7
Calcification	10.8	"	77.5
Syphilis	3.5	"	38.0

Of 87 cases in which the coronary lesion was noted as producing definite narrowing of the lumen—

Atheroma was present in	85	with fibrosis in	82 per cent
Arterio-sclerosis	31	"	84
Calcification	33	"	85
Syphilis	7	"	57

Fifty-eight of the patients died suddenly, and in ten of these there was no evidence of fibrosis. Other points which emerged from this study were: (1) severe narrowing of the artery might be present without obvious myocardial lesion. (2) severe old standing lesion and even occlusion might be present with no clinical history of its occurrence. (3) patients might die with symptoms suggesting coronary occlusion in which no such lesion was found. Disease of the coronary arteries in general tended to produce diminution of the lumen, this caused starvation of the parts supplied, followed by replacement fibrosis, or, if sudden complete occlusion occurred, infarction resulted with subsequent fibrosis. It was apparent that there could be no diagnostic symptomatology to cover all cases of coronary artery disease, in the series quoted 35 per cent of cases showed no gross lesion of the muscle, and of the remaining 238 only 58 patients could be said to have died as the immediate result of the coronary lesions. When the blockage was abrupt certain features were present with such regularity as to make diagnosis reasonably sure, these would be dealt with by subsequent speakers. The features that demanded attention were the duration and situation of the pain, the associated symptoms such as vomiting, collapse, respiratory and mental distress, and such signs as the rate and rhythm of the heart, fall of blood pressure, etc., and the information to be derived from the electrocardiogram. The ultimate prognosis was in almost all cases bad, but judging from old lesions found at necropsy, those who made a good recovery, at least temporarily, must be fairly numerous.

Dr CAREY F. COOMBS (Bristol), discussing the etiology of the two great coronary syndromes, ischaemia and infarction, gave an analysis of 1,600 cases of organic heart disease seen during the previous ten years. Both kinds of coronary attack occurred most often in the seventh decade of life, though ischaemia cordis was almost as frequent in the sixth, and appreciable in the fifth, partly owing to its relation to syphilis. Infarction was relatively more common in males than was ischaemia. Dr Coombs showed a slide indicating that cardiac rheumatism, ulcerative endocarditis, and cardiac syphilis seldom excited the coronary syndromes, except that ischaemia was more frequent in cardiac syphilis in consequence of the liability of the coronary orifices to stenosis in aortic syphilis. Some coronary disorders might, however, be traced to endocarditis lenta, and even a preceding phlebitis.

Dr IVOR DAVIES (Cardiff) commented on the importance of symptoms in disease of the coronary arteries, and referred especially to intermittent peripheral arterial claudication. Coronary sclerosis might be considered as a generic term to include angina pectoris and coronary

thrombosis. He then gave an account of the clinical manifestations and discussed the physical signs in detail.

Dr A. J. GIBSON (Oxford) dealt with diagnosis and prognosis, indicating the main features of importance with illustrative examples. He showed that when the initial lesion was not too extensive the heart could adapt itself to the structural damage, and that, therefore, if serious risks were obviated a good prognosis might be given for the immediate future.

Dr J. S. CAMPBELL (Belfast) showed a beautiful series of lantern slides of injected hearts illustrating the changes that occurred in the blood supply at different age periods. In the foetal heart there was an equal distribution of vessels to right and left ventricles, in adult life there was a much more abundant supply of vessels to the left ventricle than to the right whilst in old age this preponderance was even more striking. The second point that was clearly shown was the free anastomosis that occurred between right and left coronary arteries in cases of coronary thrombosis. In one case shown there was thrombosis of the right coronary artery, injection of the left coronary artery filled the right artery up to the point of obstruction through anastomoses chiefly in the intra-ventricular septum. The third point to which Dr Campbell drew attention was the great variation in the distribution of the two coronary arteries to the various parts of the heart, this was especially noticeable in the circumflex branches and the blood supply to the posterior wall of the heart.

Dr EVAN BEDFORD (London) referred to the value of the electro-cardiogram in the diagnosis of cardiac disease. In cardiac infarction the process of myocardial necrosis and healing could often thus be followed accurately when physical signs gave no indication of what was going on. Coronary thrombosis might simulate acute abdominal disease, and then an electro-cardiographic investigation might save an unnecessary surgical operation. Similarly in slight and doubtful cases of coronary thrombosis such an examination might materially assist the medical practitioner in enforcing rest. Professor MOORHEAD (Dublin) referred to Dr. Coombs's views as to the occasional importance of the infective factor, and related one case recently seen which had now apparently made a complete recovery. Dr GILCHRIST (Edinburgh) spoke of the association of attacks of anginal pain with paroxysmal tachycardia, and gave details of one case in which there was marked inversion of the T-wave. At necropsy there was no infarction and no thrombosis of the coronary arteries, but some stenosis at the orifice.

Sir THOMAS LEWIS, winding up the discussion, commented on the valuable ground which had been covered. He emphasized the importance of remembering the anatomical considerations.

SECTION OF SURGERY

Wednesday, July 25th

TUMOURS OF THE SPINAL CORD

At the first meeting of the Section of Surgery with the President, Professor A. W. SHEEN, in the chair, the subject for discussion was the diagnosis and treatment of spinal cord tumours.

Mr DONALD J. ARMOUR (London) limited his remarks to tumours arising from the cord, nerve roots, and the spinal meninges, and excluded tumours of the vertebral column, except chondromata growing from the intervertebral discs. He said that tumours might be either intradural or extradural without it being possible to discover the point of origin. More than three out of four spinal cord tumours were extradural, the intradural type being the commoner. Intradural tumours occupied the dorsal or dorso-lateral position in two-thirds of the cases. Clinically the course of the disease could be divided into three stages: (1) of root symptoms, usually unilateral; (2) of Brown-Séquard paralysis, and (3) of compression paraplegia. The first symptom was either pain or paraesthesia. Some cases, however, ran a painless course, or sensory symptoms appeared later in the disease. Pain, due to root irritation, was neuralgic, was referred along the course of the nerve involved, and was often increased by movements. Paraesthesia might occur at the level of the tumour,

due to root irritation, above this level, due to increased tension in the cerebro-spinal fluid or to sympathetic involvement, or, below the level, due to pressure on sensory tracts. The maximum sensory disturbance in extradural tumours was at the periphery, while with intramedullary growths this maximum of sensory disturbance was often at or below the segmental level. During the early stages of involvement of the anterior root irritative symptoms occurred, but usually when the patient was first seen these had been replaced by degenerative paralysis. Pressure on one side of the cord gave rise to the Brown-Séquard syndrome, but this soon passed into complete compression, with paraplegia or paraparesis. As the pressure increased two sets of spinal symptoms appeared—those due to the direct effect of the tumour on the involved segments and those due to pressure on the tracts of the cord. Sphincter disturbances did not appear until motor and sensory symptoms were well marked, and the loss of bladder control preceded rectal incontinence. It had been shown that the pressure effects of the tumour were limited, and that the widespread interference with the function of the cord was due to vascular disturbances. This explained the rapid recovery often seen after operation, even when the cord had been greatly narrowed and distorted. Paraplegia in flexion most frequently followed the paraplegia in extension, and this condition indicated severe and localized pressure, and in cases of tumour called for immediate operation. Intra-abdominal disease was simulated by pain due to tumours in the lower dorsal region. Lesions situated in the lumbar region presented multiple root signs, and tumours of the cauda equina gave rise to intense pain. Atypical clinical forms of the disease were referred to briefly. As regards differential diagnosis, extradural tumours grew more rapidly and gave rise to bony changes much more frequently than intradural tumours, and root pain was often absent and the vertebral column was sensitive to pressure in the case of extradural growths. The differentiation of intramedullary and extramedullary tumours was difficult, and the speaker discussed fully the various methods of distinction. With regard to treatment, Mr DONALD ARMOUR advised laminectomy after Victor Horsley's method, and did not favour osteoplastic laminectomy or hemi-laminectomy. If after opening the dura no tumour was discovered the presence of cardiac and respiratory pulsations, the condition of the posterior veins, and the escape or not of cerebro-spinal fluid should be noted. Posterior roots involved in the tumour might be divided if necessary, but every effort should be made to preserve the anterior roots. Intramedullary tumours were best dealt with by Elsberg's "extrusion" method. The speaker concluded by referring to the use of radium and x rays.

Dr GEORGE RIDDIOCH (London) briefly discussed the clinical aspects of the disease. He said that paraplegia, whether due to intramedullary or extramedullary lesions, followed a very definite sequence—spastic paraplegia in extension, followed by paraplegia in flexion, and finally flaccid paralysis. With anterior tumours flexion paraplegia might occur first. Focal signs of the level of the lesion were radicular and segmental. They were absent sometimes with ventrally placed tumours and small tumours between the roots. The importance of finding the level of the junction of abnormal and normal sensation was mentioned, but the crossing of the sensory fibres must be borne in mind. He briefly referred to the differential diagnosis of extradural and intramedullary growths.

Sir PERCY SARGENT (London) said that lipiodol gave rise to severe root pains in some cases, he wondered whether there would be some changes of the membranes of the cauda equina in after years due to the prolonged presence of this iodine-containing preparation. When clinical and other methods were satisfactory for diagnosis and localization in a given case he stated that lipiodol should not be used. The speaker had had no success with the light solution of lipiodol. Referring to the differential diagnosis of intramedullary and extramedullary tumours he said that the number of segments and the elongated blockage of the canal helped to decide this point. Mere dissociation of sensation was of little use for differential diagnosis. Sir Percy Sargent said that the prognosis of intramedullary tumours was not so bad as was thought. The mortality

rate of operation was low, the worse prognosis was given in growths from the second to fifth thoracic segments, where cardiac disturbances followed the operation. Lower down acute dilatation of the stomach occurred, and lower still intestinal paralysis supervened. Slides were shown of neurofibromata and endotheliomata, also x-ray photographs of lipiodol injections.

Mr GIFFORD JEFFERSON (Manchester) said that pain was not a common complaint in his cases, but spastic paraplegia. He divided spastic paraplegia into (1) a degenerative type and (2) a compression type. There was considerable difficulty in distinguishing these groups, but the picture of cord compression with its definite sequence was often clear cut. He had used Queckenstedt's test with success to diagnose complete blockage of the canal. Excellent diagrams were shown illustrating the value of this test even in cases of partial blockage. Testing the cerebro-spinal fluid was also important, since stasis due to the blockage increased the albumin content.

Mr LAMBERT ROGERS (Cardiff) reported a case of complete and rapid recovery after removal of a meningioma, though the spinal cord was flattened out into a tapo-like form. The tumour, as well as containing the psammoma bodies, contained true bone. Mr Rogers showed some interesting x-ray photographs after lipiodol injection.

Mr WILFRID TROTTER (London) disagreed with Mr Jefferson that pain was not a common and early feature. Cases of spinal tumours were missed until a patient with an unexplained pain, which was mistaken for many other diseases, developed paresis. He said that Sir Percy Sargent stated that neurofibromata were the commonest tumours, and these gave rise to intense pain with few or no physical signs. It was of vital importance to investigate these pains thoroughly, especially the character, position, and distribution of the pain, and the influence of coughing, etc., on it. Patients should come to operation after a definite diagnosis was made, long before there were paralytic signs and symptoms. Mr ADAMS (Bristol) reported one case in which there was no pain, but merely a slight limp on walking. He suggested that neurofibromata might cause root pains, while endotheliomata produced motor signs and symptoms. Mr STANLEY FOSTER (New Zealand) agreed with Mr Trotter regarding the sensory symptoms. Mr BROCKMAN (Sheffield) said that pain due to spinal tumour should be kept in mind when a patient came with a curious unexplained pain.

Mr ARMOUR, replying, said that he agreed that the upper dorsal region was the dangerous zone. The period of early pain was certainly the correct time for treatment. He mentioned that Professor Sicard now advocated immediate screening after injection of lipiodol.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Wednesday, July 25th

UNSUCCESSFUL FORCEPS CASES

The first meeting of the Section, under the presidency of Dr T. W. EDEN, was devoted to a discussion on unsuccessful forceps cases, a subject which was introduced during the final meeting of the Section last year too late to permit of adequate consideration. The opening papers, by Dr Douglas Millar (Edinburgh), Professor James Hendry (Glasgow), and Professor W. Fletcher Shaw (Manchester), were printed in this issue.

The President remarked that Dr Miller had had results of three hospitals at his disposal. His account should be regarded as the standard picture of what was going on all over the country. Those present could realize how great the evil was.

Dr C. E. DOUGLAS (St Andrews) spoke on behalf of the general practitioner. He had only meant to make a plea for version in failed forceps cases. He could look back for forty years, and much that happened then should not happen now. Now we had ante-natal supervision. A great future lay in front of the general practitioner if he would take advantage of it. He and he alone should be the person to do this work. In the paper version had been employed in only 5 per cent of the cases. All could apply version if they had a reasonable degree of skill. The only

safe rule was to do nothing at all until the os was suitably dilated, to do otherwise was courting disaster. Manual dilatation of the os should be relegated to the scrap-heap. With chloral and patience the os would dilate itself. He had had nine cases of failed forceps, eight were occipito-posterior cases. There were no maternal deaths, but four babies had died.

Dr BIRNELL SOLOMONS (Dublin) said that it seemed extraordinary that no one was excited at the figures presented. There were two definite causes: (1) blissful ignorance—to be cured by better training, (2) wilful negligence. A man should be thrown out of the profession for applying forceps too early. The application of tentative forceps, with a view to possible pubiotomy or low Caesarean section, was quite justifiable. Post-graduate training should be insisted on: five years was far too short. In Sweden eight years was the minimum. X-rays were very useful in confirming the diagnosis. He did not think it was possible to diagnose a living child, and it was dangerous to think it was. As for Caesarean section or craniotomy, he preferred the low Caesarean operation as safer than craniotomy. A live child should never be killed. The lower segment operation with drainage was quite safe. Few cases of failed forceps occurred in Ireland. There was no mystery about this subject, and they should be perfectly able to grapple with it. In regard to adequate payment, a composite fee to the family doctor should be paid. He suggested that what was wanted was strength of mind to avoid forceps when contraindicated, and strength of arm to deliver when forceps were indicated.

Dr MADEL RAMSAY (Plymouth) lived in a district where there was no maternity hospital. She asked how long a trial labour should be—should it be two or three days? In private practice she had many more worries than in her Poor Law hospital, where she had the help of an excellent midwife. Craniotomy gave her a feeling of horror, she had never performed this operation. She had no fear of doing a Caesarean section if she had been in attendance on the case herself. Ante-natal schemes were very well, but the patient failed because she would not pay the fees. The fee question bulked very largely. Maternity and child welfare officers were not adequately trained. In future not only ante-natal, but post-natal work also, would have to be done. Mr L. C. RIVETT first of all urged the extreme importance of ante-natal care. Secondly, he agreed with the tentative application of forceps. He wished to emphasize that (1) the head must be engaged in the pelvic brim, (2) the cervix must be fully dilated, (3) the bladder must be empty, (4) uterine contractions must be present, before any attempt be made to apply forceps. He did not agree with attempting version or embryotomy after all the liquor had drained away. Caesarean section was much safer when the uterus was in an irritable state. There was less shock than in embryotomy. With regard to the training of students, he thought that six continuous months was the very minimum in which to teach them midwifery. Dr KELSON FORD (Preston) thought that a composite fee should be charged, to include ante-natal supervision and attendance at confinements. He asked how it was that eight cases of ruptured uterus occurred, whereas only three Caesarean sections were reported. In the elderly primipara the fate of the baby was as important as the fate of the mother. He did not think that the possibilities of Caesarean section in definitely infected cases had received sufficient attention. He found that it was easier to get patients to attend for ante-natal supervision than for post-natal examination. He thought it was a debatable policy for general hospitals to open beds for normal midwifery, but that this work should be undertaken by special State-aided institutions.

Mr TENISON COLLINS (Cardiff) said that a certain proportion of cases might be avoided if patients were not allowed to go over their time. They were constantly seeing cases where forceps had been applied too soon. The public thought that the best doctor was the one who produced the child in the shortest time. Much good would be done if it were being constantly brought to public notice that time must be given. Dr KENNETH WILSON (Blandford) agreed that it was impossible to obtain a fee for ante-natal work in country districts. He thought payment should

come from the State. He had had one case of failed forceps. He had attended this patient in two previously normal confinements. In this case he came to the conclusion that hydrocephalus was the cause. He performed craniotomy, and she subsequently developed puerperal insanity, but quickly recovered. In another case the head was floating freely after forty-eight hours of labour. Under anaesthesia he pushed the head easily into the pelvis. After sixty hours there was still no further progress. Six hours later, there being no progress, Caesarean section was performed, and it was found that the whole uterus was spotted with multiple small fibromyomata. Mr. PARSONS (Rugby) spoke in favour of pubiotomy. He had performed the operation seven times with one maternal and two foetal deaths. Haemorrhage might be rather alarming, and laceration of the perineum and vagina might be considerable. He advocated chlorine douches, given before and after delivery. Dr. BOYN (Manchester) supported the application of version. In 1,500 cases he had had many where forceps had failed and version had succeeded. It had to be confessed that many foetal deaths had to be recorded. He deprecated the sweeping statement that these cases were all due to ignorance or neglect. Dr. QUINN (Dublin) reminded the meeting that no slums could be worse than the slums of Dublin, and the Master of the Rotunda had to have a long apprenticeship in these surroundings. Not enough stress was laid, in teaching, on the normal case. If non-interference in normal cases were practised Nature would do the rest. The high foetal mortality was caused by injudicious attempts at treatment. He emphasized the value of morphine at the commencement of labour. He did not approve of the use of lysol.

Miss FRANCES IVENS (Liverpool), while in considerable agreement with much that had been said by the openers, wished to bring forward some points based on an analysis of twenty-six failed forceps cases admitted to her department at the Liverpool Maternity Hospital during the last seven years. Of these, two delivered themselves (both children alive), nine were delivered by medium or low forceps, with seven living children, two by high forceps (one living child), six by Caesarean section, with four living children, six by craniotomy and one by version, all stillbirths. In no case was craniotomy performed on a living child, and potential sepsis was not regarded as a bar to a classical Caesarean section (in one case forceps had been attempted four times). One mother out of the twenty-six died, delivered by Caesarean section after two forceps attempts. Her death was due to *Staphylococcus aureus* septicaemia, the source of infection being possibly from her husband, who was suffering from boils, she had been to a clinic, but had refused examination. Dr. Miller's figures indicated that the high mortality in failed forceps cases was largely due to sepsis, and Miss Ivens's figures corroborated this. Thirteen—that is, one-half—of the cases were morbid. A streptococcus and *Bacillus coli* were present in five cases, a non-haemolytic streptococcus in two cases, a streptococcus and the *Staphylococcus aureus* in one case, a streptococcus, *Staphylococcus aureus*, and *B. coli* in one case and in a case where the child was gangrenous, *B. coli* and *B. welchii*. To combat this risk of infection special precautions were taken, antistreptococcal serum being given at the time of delivery by Besredka's method—namely, with a large quantity of normal saline. This was followed whenever possible by the serum appropriate for the infection. Some Weinberg anti-gangrenous serum which had just arrived from the Pasteur Institute, was undoubtedly instrumental in saving the life of the patient with gas gangrene infection. Good uterine retraction was obtained by the use of pituitrin and ergotin. In the cases of Caesarean section drainage into the cave of Retzius was employed, and steps were taken to obtain early and free bowel evacuation. In regard to the source of infection, the frequent presence of a non-haemolytic streptococcus and *B. coli* suggested an intestinal origin. The speaker made it a rule that there should be no vaginal examination until the patient had been given a bath and the vulva shaved and thoroughly washed down over a douche pan. She emphasized the undesirability of making internal examinations either in ante-natal clinics or elsewhere very late in pregnancy without taking special precautions. She

agreed with those who believed in correcting the posterior position, and always advised the exaggerated Sims's position. She thought ante-natal teaching was beginning to bear good fruit, and there was a big field waiting for those doctors who would perfect themselves in it, so that the normal cases could be left to the midwives whilst the borderline cases might be more carefully watched or sent into hospital. Also, the education of students in midwifery was better, and the more recently trained graduates were realizing how easily a case could be spoilt for Caesarean section. She did not think that remuneration had much to do with the quality of medical work. If it had, the honorary work carried on in voluntary hospitals would not be so highly valued as it was.

Replying to the discussion, Dr. MILLER referred to the criticism of the expression "dying child." He agreed that this description was misleading. The cases he had in mind were those in which fractures of the foetal skull could be detected. The small number of failed forceps cases admitted to the Rotunda spoke volumes for the teaching there. He explained the apparent discrepancy in the figures applied to rupture of the uterus and Caesarean section. Professor HENDRY referred to a case to illustrate what he meant by a test labour. It was a very serious matter when patients did not turn up for ante-natal examination. It was difficult to say when forceps had been applied tentatively. He agreed with what had been said about attempting version or craniotomy when the uterus was irritable and the patient was suffering from shock. He did not advocate instrumental rotation, but much preferred manual rotation. He objected very strongly to remarks deprecating the value of x-ray ante-natal examinations. Mr. FLETCHER SLAW said that ante-natal work was carried out in Manchester as a routine long before Dr. Ballantyne had published his paper from Edinburgh. Lysol had done more harm in midwifery than anything else, it was not used in sufficient strength. With regard to fees for ante-natal treatment, these should be composite to cover everything. The ideal way would be for the doctor to have care of the patient before labour, the midwife to attend the normal confinement, the doctor to attend again during the puerperium.

SECTION OF MENTAL DISEASES AND NEUROLOGY

Wednesday, July 27th.

AUTOTOXAEMIA AND THE PSYCHOSES

Dr. EDWIN GOODALL, President of the Section, in a brief introductory speech, referred to the achievements of Professor W. Weygandt, the opener of the discussion on autotoxaemia as a factor in the causation of the psychoses. Professor W. WEYGANDT (Hamburg) remarked that in the course of the past century a great change had taken place in the doctrine of the causation of psychoses, it had become more firmly settled that mental derangements were cerebral diseases, and that a morbid influence on the brain represented the cause of mental disorders. In 1896 Kraepelin described dementia praecox as a metabolic disease, and called attention to an inherited disposition in 70 per cent of cases. The realization that an endogenous cause of the disease must be assumed had induced an intensive investigation of the blood and endocrine glands. Professor Weygandt then considered in detail the forms of retarded evolution in relation to endocrine metabolism. One of the most important problems of psychiatry was to determine the pathogenesis of dementia praecox, or schizophrenia. In 70 per cent of cases there was an inherited factor. Pathological changes were found in certain cerebral cells, especially those of the third cortical stratum. The fifth and sixth strata also might exhibit atrophy, while von Monakow claimed to have found changes in the choroid plexus. The basic conditions of manic-depressive psychosis (cyclothymia) he considered entirely different. The inherited factor in this was most important, and could be traced in 90 per cent of cases. There was no question of an anatomical basis, and in his opinion we could not attribute great importance to the factor of autotoxaemia. Generally speaking, there was present an instability of affective mind caused by heredity, and possibly connected with vasomotor fluctuations. Autotoxaemia was of great importance in

truo or cryptogenic epilepsy, as distinct from symptomatic epilepsy. As regards treatment, the facts discussed had been put to abundant use. Thyroid preparations were successful in the treatment of myxoedema and cretinism, while results in pituitary disorders were possible by x-ray treatment and glandular feeding. Malarial or pyrexial treatment had as yet no apparent success in dementia praecox, epilepsy, etc. Weissen had treated the endocrine glands with x-rays in 28 cases of idiocy, including Mongolism, and in 54 cases the clinical condition and quality of the serum reactions had improved. Diagnosis, as well as therapeutics, demanded that research in the antotoxaemic influences in psychoses was to be regarded as one of the most important tasks of psychiatry. Dr PICKWORTH showed slides illustrating sphenoidal sinusitis and its relation to pituitary disturbance, in order to suggest that many symptoms of metabolic disorder were referable to dysfunction of a small portion of the brain near the pituitary stalk.

Dr E. MAROTER suggested that Professor Weygandt's paper would have been better entitled "Anomalies of metabolism associated with psychoses." He thought all were equally agreed that every mental process was only the subjective aspect of a bodily one, which left traces and originated habits and reactions. As regards gross endocrine abnormalities and mental disorder, he believed that in most cases, with the possible exception of the thyroid, the suggestion was rather one of frequent occurrences than of causal dependence. Sexual disturbances and the psychological reactions arising therefrom appeared to have more psychiatric importance than all the rest of the endocrine disorders. Such conditions as erotism and nymphomania on the one hand, impotence and frigidity on the other, were extremely common, and the reactions arising from these conditions were important.

Dr I. S. WILK (New York) considered that the terms toxæmia and psychoses were employed in too broad connotation, they could not disregard heredity and infectious endocrine disorders and psychoses might be due to a common underlying cause, as syphilis, he concomitant, as in presence of cerebral tumour and diabetes, he in causal relation, as mental enfeeblement and athyroidism, be co-existent, but with variation in time and intensity without causal relation. It was necessary to show causal relationship rather than coexistence of symptoms. In his opinion the distinctions between the biochemistry of psychoneuroses and psychoses were not marked or clear. Dr MAX BARKAS said that the association of these physical disorders with mental disease might be explained otherwise than as direct causes of psychoses, and that the psychiatrist might promote the development of psychiatry far more by concentrating on the study of the mental processes of patients than by a flight into the laboratory. She believed that autotoxaemia and similar disorders might be related to mental disorder in the following ways: (1) as a precipitating factor, (2) as a source of mental stress, (3) as joint effect of some primary cause, (4) as chance concomitant, and (5)—and most important—as the result of the mental and emotional or psychomotor disorder. Moreover, Dr Barkas thought they should consider whether the attempts at cure which were based on the bodily changes they found might not act indirectly through the mind, rather than directly through the body. Finally, she suggested that another factor should be considered in this relation of cause and effect. In many psychotics a sense of guilt and craving for self-punishment played a prominent part, as was often seen in attempts at self-mutilation or self-destruction. This might well be a factor in decreasing the resistance to disease. If these considerations were valid, Dr Barkas thought it evident that investigation of the mental state of the insane was at least as likely to throw light on the causation of mental disorder as was laboratory research. She would urge that for the majority of asylum medical officers clinical psychiatry offered a far more fruitful field.

Dr R. D. GILLESPIE said that the conception of autotoxaemia in this country had been restricted largely to conditions of supposed intestinal absorption. The bacteriology of the colon in persons mentally normal was in too vague a condition to make it safe to draw definite con-

clusions from a bacteriological examination of the faeces in the psychoses. Similarly, regarding Dr Pickworth's work, it was very dangerous for him to argue from his interesting findings to the psychoses in general. Regarding intestinal toxæmias, Dr Gillespie said that clinical experience with Hirschsprung's disease showed that mental symptoms were usually absent in spite of the extreme stasis, when they were present they were of the confusional type. Ulcerative colitis, when absorption certainly occurred, was not associated with mental symptoms as a rule, whereas mental symptoms of a kind accompanied the so-called mucous colitis, when absorption was probably absent. Dr HELEN BOYLE (Brighton) remarked that it was cheering that Professor Weygandt talked of recovery in dementia praecox. Clinicians would agree with him that some such patients appeared to recover. From his paper there seemed to be hope that some of his tests might serve to distinguish these cases from others. It was not satisfactory to assume merely that it was faulty diagnosis should recovery take place. With regard to manio-depressive states, she said that many patients seemed to show an association with Graves's disease to a marked degree.

The PRESIDENT remarked that acute and recent cases admitted into mental hospitals and clinics were well known to improve in large measure with a preliminary enema or two, and systematic colonic lavages. The same applied to obstructions in habits of mental hospitals. Admittedly these cases were not pure instances of auto-intoxication. There had been published, from the laboratory at Cardiff, work upon the distribution of the various nitrogen constituents of plasma, cerebro-spinal fluid, and urine in some forty, mostly newly admitted, cases of mental disorder. All were males, excepting eight, the ages ranged from 21 to 52 years. They found that non-protein nitrogen was high in the plasma, that urea nitrogen tended to be low, that the amino-acid nitrogen was low. These conditions were irrespective of the type of case. In fourteen cases the unknown nitrogen—which was got by subtracting the sum of the various non-protein nitrogen constituents estimated from the total non-protein nitrogen—was high in the plasma. It formed 20 to 40 per cent of the total non-protein nitrogen (a high proportion). With the high non-protein nitrogen and the frequently high urea nitrogen in the plasma went a low total nitrogen and urea nitrogen in the urine. The above results appeared to point to anomalies of protein metabolism in the mental cases studied. Of late years little had been heard of the Abderhalden method in psychiatry, and, therefore, it was very significant that the method of Abderhalden was now believed to give a positive result with the blood of schizophrenic patients, with cerebral cortex, gonads, and often with thyroid and pituitary. If these things were so there should surely by now be a welcome means of diagnosis between true schizophrenia and recoverable states resembling such. They had at the present time under investigation at the Cardiff Mental Hospital laboratory the relation of anti-substances in the blood to testicular and thyroid extracts, using rabbits for inoculation with the latter.

SECTION OF PATHOLOGY AND BACTERIOLOGY

Wednesday, July 25th

ENCEPHALO-MYELITIS IN THE COURSE OF VIRUS DISEASE AND THE EXANTHEMATA

At the opening meeting of this Section the chair was taken by the President, Professor E. H. KITTLE, who called upon Professor H. M. Turnbull to introduce the discussion on encephalitis. Professor TURNBULL gave a detailed account of the histological appearances, dividing them into acute and subacute types. He distinguished thus post-vaccinal encephalitis from poliomyelitis and encephalitis lethargica, assigning it to the group of conditions characterized by demyelination. Similar histological conditions had also been observed in other conditions, such as chronic gonorrhoea, and in affections of the central nervous system complicating exanthemata.

Professor JAMES MCINTOSH described an experimental and pathological study of encephalo-myelitis as found in encephalitis lethargica, small pox, and after vaccination. Vaccinal lesions in the brain were more meningeal than

encephalitic, and frequently showed large areas of necrosis. He gave reasons for indicating a vaccinal etiology in these conditions, and defined the differences between the vaccinal lesions and those of poliomyelitis and encephalitis lethargica.

Dr J G GREENFIELD, whose paper was read by Professor HADFIELD, had examined a case of fatal encephalitis following measles. In this patient, four days after the fall of the temperature to normal, there were fever, coma, convulsions, and death within thirty-six hours. The histological changes found in the brain were a universal perivascular infiltration of a diffuse type, including a number of plasma cells, and perivascular demyelination, which was strictly confined to the white matter, occasional deposits of free stainable fat were demonstrable in these areas. The changes thus closely resembled those of post-vaccinal encephalitis.

Dr S PHILLIPS BEDSON discussed the hypothesis that post-vaccinal encephalitis was actually due to the virus of herpes activated by vaccination. This virus had been found in the brains of nine cases of epidemic encephalitis examined by Levaditi and in three examined by Peidrau. He rejected this hypothesis on the grounds that no herpetic eruption occurs in encephalitis, that in pneumonia, malaria, and cerebro-spinal fever, which frequently activate the virus with the production of a herpetic eruption, encephalitis is unknown, that no antibodies to the virus are demonstrable in the blood from cases of encephalitis, and, finally, that the virus had been found by Flexner in the cerebro-spinal fluid from a case of cerebral syphilis. He referred to the difficulty of working on this subject with rabbits owing to the existence of two other varieties of encephalitis in the rabbit itself, and suggested that the resources of an institute devoted wholly to this subject could alone cope adequately with the problems involved.

Professor G HADFIELD (Bristol) had examined the brain of one case of post-vaccinal encephalitis which showed lesions similar to those described, and four brains from children dying from other causes between the eighth and fourteenth days after vaccination, in none of which were any histological abnormalities demonstrable. He emphasized the need of defining accurately the histological picture in post-vaccinal encephalitis, its most salient feature hitherto demonstrated was the rapidity of myelin destruction, and the absence from some demyelinated areas of any cellular infiltration. A possibility of further distinguishing the changes from those of other forms of encephalitis lay in the more minute study of the type of cellular infiltration, and of the nature of the microglial reaction.

Professor J H DIBLE (Cardiff) regarded all the positive results obtained in work on lethargic encephalitis with rabbits as invalidated by the possibility that the lesions in rabbits were due to the virus of herpes. This hypothesis was supported by the fact that brain material from cases of human encephalitis does not produce ketatitis in rabbits, whereas this lesion can be produced with the brain of a rabbit succumbing to encephalitis after being inoculated with the same material. Discrepancies in the incubation period which varied from three to sixty days, when attempts had been made to transmit the disease to monkeys, taken in conjunction with Flexner's failure to produce the disease in monkeys at all, cast a similar doubt on the work which had been done with this animal. It was his belief that transmission of this disease to animals had not yet been accomplished.

Dr C FORBES observed that the word "virus" had been used in different senses, and urged that the precise definition of pathological terms should be periodically reviewed. Dr BARCROFT ANDERSON asked whether in post-vaccinal encephalitis, and in the encephalitis of measles, there was any diminution in the lytic power of the blood for bacteria in general. Professor J CRICKSHANK (Aberdeen) observed as a noteworthy fact that herpes occurred in diseases of ordinary bacterial origin, and encephalitis in diseases believed to be due to a virus. He asked whether the calves used in the preparation of lymph were known ever to suffer from encephalitis. As bearing on the question of whether the agent producing the encephalitis was in the lymph or in the patient, he quoted an observation of Levaditi's, that a hatch of lymph used for many thousands of cases in

Spain without causing any encephalitis produced this complication in a number of patients in Holland.

Professor TURNBULL, in his reply, expressed interest in the case of measles described by Dr Greenfield, and in the controls examined by Professor Hadfield. Professor McINTOSH said that he regarded encephalitis due to the virus of herpes as clearly distinguished by the changes in the parenchymatous cells of the brain. His general convictions were summed up in the statement that all exanthemata may be complicated by encephalitis, and that the encephalitis was due in each case to the virus of the exanthem itself.

The PRESIDENT, in summing up the discussion, thought it had done much to clear their ideas on this difficult subject. There seemed no doubt that a form of encephalitis was definitely associated with vaccination, and the evidence seemed to show that it was directly due to the vaccino virus. But from the practical point of view it did not greatly matter whether the vaccination actually caused encephalitis or whether it merely lighted up a latent infection. If an individual suffering from heart disease was assaulted with fatal results his assailant could not escape punishment by the plea that the violence offered was insufficient to kill a healthy man. Similarly, vaccination could not be held blameless if it lit up a latent infection. The possibility of encephalitis following vaccination could not be denied, and he had hoped that the discussion might have brought out some official information as to the number of fatalities associated with vaccination in recent years, so that the medical practitioner might be able to reassure the public, which was already fully informed of the complication by the lay press.

SECTION OF DISEASES OF CHILDREN

Wednesday, July 25th

CHRONIC SPLENOMEGALY IN CHILDHOOD

Dr ALFRED HOWELL (Cardiff), President of the Section, took the chair at the first discussion of this Section, which dealt with chronic splenomegaly in childhood, with particular reference to diagnosis and treatment. Dr ROBERT HUTCHISON opened the discussion by emphasizing the points in diagnosis of splenic enlargement, and mentioned the difficulties which might arise with a tumour in the splenic region, proceeding to consider the different varieties of splenomegaly in childhood tumours, including cysts, new growths, abscesses, etc., were very rare. Of the chronic infections tuberculosis, syphilis, lymphadenoma, and chronic sepsis had to be considered. In the acute form of tuberculosis in young infants enlargement of the spleen was very common. With regard to congenital syphilis he thought that its frequency as a cause of splenomegaly was exaggerated. In pre-Wassermann days every splenomegaly of doubtful origin was ascribed to syphilis, but the test was very often negative in these circumstances. Lymphadenoma causing splenomegaly without enlargement of glands anywhere was very rare. Chronic sepsis was blamed for splenomegaly, but on rather doubtful grounds. The tropical diseases and splenomegaly presented the same features as in adults. Enlargement of the spleen in metabolic disorders chiefly meant the part that rickets played in causing such enlargement, here again the importance of rickets as a factor in producing splenomegaly was probably exaggerated. Gaucher's disease might also now be included under the metabolic disorders, and was to be diagnosed by finding the characteristic endothelial cell in splenic puncture fluid. The value of splenectomy in such cases was disputed. Splenomegaly in diseases of the blood formed a big group. The leukaemias in childhood were almost always acute and therefore not a cause of chronic splenomegaly. The splenic anaemia of infancy (von Jakseh) was apparently becoming rare. Dr Hutchison believed it to be a disease *sui generis*, and said the blood picture during the acute phase was characteristic. The disease tended towards spontaneous recovery, and this must be remembered in considering treatment. In acholic jaundice splenomegaly was well recognized, and splenectomy was the only effective form of treatment. Splenomegaly was not likely to be a presenting sign in purpura even in the chronic forms. True erythraemia probably did not occur in children as a cause

of splenomegaly. The next group of cases was very interesting—splenomegaly associated with cirrhosis of the liver, of which three varieties (excluding Banti's disease) were recognized. Idiopathic non-alcoholic progressive cirrhosis, resembling the ordinary portal cirrhosis of adults, was always associated with enlargement of the spleen to some degree, in these cases the value of splenectomy was debatable. The second variety was syphilitic cirrhosis associated with splenomegaly, met with in later childhood. The third group consisted of splenomegaly with biliary cirrhosis, believed to be the form which Hanot's cirrhosis took in the child. Another group of cases with chronic splenomegaly in childhood was the result of thrombosis of the splenic vein. The treatment of splenic anaemia of the adult type was splenectomy, but opinions differed as to the value of operation once cirrhosis of the liver had supervened. Dr Hutchison then suggested some points for discussion, and summed up the question of treatment.

Mr L E BARRINGTON-WARN said that the surgeon usually saw cases of splenomegaly when the diagnosis had already been made by the physician, who had generally decided that the spleen ought to be excised. Splenectomy was, incidentally, not so very frequently performed, for in the last ten years at Great Ormond Street the operation had only been employed on ten occasions, in each case for acholuric jaundice. From a surgical point of view, splenectomy was required in two groups of cases. First, where a cure or amelioration of symptoms was expected, as in tumours, localized infections, and abscesses, all of which were rare, but instances of which had been recorded. In this group also came chronic familial haemolytic jaundice cases and cases of thrombocytopenic purpura haemorrhagica. The second group consisted of cases in which there was some hope of bettering the patient without real cure. In Gaucher's disease there were apparently only four cases in which successful removal of the spleen had been carried out in children, and in such cases splenectomy as a palliative operation was justifiable. In Banti's disease, which Mr Barrington-Warn believed did occur in childhood, he pleaded for earlier removal of the spleen. He had no personal experience of splenectomy in von Jaksch's anaemia. In operating upon cases of splenic vein thrombosis great difficulties were experienced owing to the large efferent vessels connecting every surface of the spleen with adjacent organs. Dealing lastly with splenectomy as an operation, the speaker said that blood transfusion before and after was essential in every case, and retransfusion of the splenic blood was also valuable. He had no experience of preliminary irradiation of the spleen, but W S Mayo spoke highly of it. "Gas and oxygen" was the anaesthetic of choice, and the left paramedian incision was the most useful.

Professor L FINDLAY (Glasgow) agreed with Dr Hutchison that rickets did not play an important part in the production of chronic splenomegaly. Since the spleen could not be embraced the true state of its size was difficult to estimate, and all conclusions were drawn from its degree of palpability. The normal spleen could be displaced downwards by tumours, including enlargements of the liver, and also by deformities of the chest. He had never seen an enlarged spleen in rickets unless complicated by anaemia, syphilis, tuberculosis, or severe deformity of the chest. He had once seen the spleen as the only palpable evidence of tuberculosis, when the diagnosis was made by splenic puncture. Professor Findlay agreed that the incidence of congenital syphilis had been overestimated, and this accounted for only a small number of splenomegalies. Nevertheless in the presence of anaemia and enlarged spleen, syphilis must be eliminated in every case, and he placed great faith in the Wassermann reaction when properly carried out. He had seen a palpable spleen as the only evidence of lymphadenoma, which was diagnosed at autopsy. With regard to splenectomy in such conditions as Von Jaksch's anaemia he had never seen it do any harm, but there was no sudden alteration in the blood picture, such as occurred after splenectomy in Banti's disease and the operation apparently interfered little with the natural course of the disease. With regard to the relation of splenomegaly to cirrhosis of the liver and the place of Banti's disease Professor Findlay thought that

the cases described by Dr Hutchison would do for either condition. In the past the tendency had been for many pathological states to be included under one heading, but now one pathological state was given more than one name. In Banti's disease cirrhosis was present from the earliest stage, but the presence or absence of ascites varied greatly and caused much confusion. What was needed was a careful study of clinical and pathological findings in a large series of such cases. Whatever the truth of the pathological condition the procedure in coming to a diagnosis was, however, certain—a complete blood count, a Wassermann reaction, fragility estimation, and a splenic puncture (unless splenectomy was immediately contemplated) were essential in every case.

Dr O PAGET LAPAGE (Manchester) agreed that the difficulty of diagnosing an enlarged spleen was not small, and he described cases where a tuberculous omentum and a kidney tumour had caused uncertainty. The nature of the enlargement gave some help, the hard "pane-like" spleen of von Jaksch's disease and the nodular enlargement of new growth or lymphadenoma were characteristic. He went on to deal with twenty-two cases of von Jaksch's anaemia which he had seen during the last sixteen years. The disease had certainly diminished in frequency, but was now increasing again. In his series of cases Dr Lapage said the family history was good, syphilis played no part, the sex incidence was equal, all were under 3 years of age, and two cases occurred in twins. There was a history of dyspeptic disorders in many cases, and rickets also occurred, probably as a secondary condition. Bruising and purpuric spots were present in certain cases, but leukaemia had to be considered if the purpura was very marked. The temperature was not raised. The blood picture varied very considerably, and there was a large personal factor in making the blood counts. In treatment he employed arsenic, and sometimes benzene, and recently he had tried liver on one case with apparent improvement. In following up his cases Dr Lapage found that eleven patients had been discharged improved, one of whom had subsequently died, five were discharged *in statu quo*, but at least two of these had made a good recovery. Two cases had died in hospital. In view of the fact that on the whole patients did well he was not inclined to recommend splenectomy. Dr J W SCOTT (Nottingham) said that with regard to splenomegaly and chronic sepsis he had seen cases with arthritic changes in which chronic pyogenic infection was believed to be the cause. In cases with haematemesis and enlarged spleen he found the diagnosis difficult. In two cases recently seen the patients had been in good health when haematemesis occurred with a rise of temperature and slight ascites, and he considered that some active condition was present, possibly a perisplenitis. The shrinkage which followed haemorrhage also supported this, as did the condition of venous anastomosis found at operation. He said that there were cases of enlarged spleen with anaemia in which everything else was normal, and they did very well.

Dr HILDA STROSSIGER described a case of splenectomy for Banti's disease in a boy aged 14, who was under the care of Dr Branson at the Royal Free Hospital in 1926. Before operation the patient had complained of abdominal discomfort for a few months, and slight anaemia, leucopenia, and a negative Wassermann reaction were present. A levulose tolerance test showed marked hepatic inefficiency, and at operation cirrhosis was well marked. Two years later the boy was very well, growing quickly, but puberty was delayed and hepatic inefficiency was still marked. Dr L G PARSONS (Birmingham) commented on the difficulties of diagnosis of splenic enlargement. He had felt typical notching on a mass of tuberculous glands, and he had never found the traditional colonic resonance over a splenic tumour. He was especially interested in the cases of splenomegaly with hepatic cirrhosis. Wallgren's type with splenic vein thromboses had not been mentioned in the discussion at the Royal Society of Medicine in 1925, but two cases which he, Dr Parsons, had then described as cases of Banti's disease had been claimed by Wallgren as examples of his syndrome. The differentiation was very difficult, and the only point between Banti's disease and "cirrhosis with splenic predominance" appeared to be that the latter was more rapid in its course. The question
